During the war the House was accepted by the Government for the use of convalescent sailors and marines, one hundred beds being provided. At this time the adjoining estate of twelve acres, with a beautiful country house with all its appurtenances, had been made ready for the soldiers.

The service of St. Francis to the country during the World War was formally acknowledged by W. C. Braisted, surgeon general of the United States Navy, in the following letter, written under date of December 15, 1919:

"The Bureau has had official reports from the commanding officer of the Naval Base Hospital of the services rendered by your hospital during the World War, and of the great assistance afforded by your staff, including doctors, nurses, and employees, in the case of the sick and injured officers and enlisted men of the Navy and the Marine Corps.

"The period during which this assistance was rendered covered not only the active period of the war, but extended beyond the date of the signing of the armistice; the help given was of such a character as to indicate a high standard of efficiency throughout your institution, both as to personnel and equipment; and the arduous duties performed so cheerfully make the loyalty and patriotism of all concerned.

"With a full appreciation of the valuable aid rendered in meeting that part of the war situation which fell to the lot of the Medical Department of the Navy, the Bureau desires to extend to you its sincere thanks for your assistance."

STUDIES IN ARTHRITIS*

PEMBERTON and his co-workers in the Army Hospital at Lakewood had an unusual opportunity of making an intensive investigation of the problem of chronic arthritis as presented by four hundred cases in soldiers. The results of these investigations are now appearing. Sixty-four per cent had arthritis only; 28 per cent had a combination of arthritis and myositis; 5.5 per cent had myositis only; 1.75 per cent had neuritis. The precipitating factors include 58 per cent due to exposure; 8.25 per cent due to dysentery; and a gradually diminishing percentage due to injury and other causes. Approximately 35 per cent of all the cases had had previous attacks of "rheumatism," in contrast to a percentage of only seven in non-arthritic army patients. The knee, ankle, hip, and shoulder were the most common sites of involvement. Nearly 75 per cent showed demonstrable surgical foci of infection, 52 per cent of the entire series being in the tonsils, while 33 per cent showed a dental focus. However, the relationship of these foci to the arthritis must not be accepted as causal. The etiological aspect of exposure to cold and wet is so pronounced as to leave little doubt concerning the cause and effect relationship. The number of cases resulting from hiking and other physical demands of the training is very small. One most interesting point brought out by Pemberton is that even in the presence of demonstrable foci of infection 46 per cent of their arthritic cases recovered without removal of the focus.

Metabolic studies were made with the Tissot calorimeter. The figures obtained for basal metabolism in most instances did not vary from the accepted normal standards. The nitrogen, urea, carbon dioxid combining power of the blood, calcium of the circulating blood, total fat and cholesterol of the fasting blood were well within normal limits. The renal function as tested by the Mosenthal diet shows no marked variations, although Pemberton thinks that a very slight lag in the elimination of water, nitrogen, and salt is indicated by the results of his investigations.

Pemberton for sometime has claimed that in chronic arthritis there is present a diminished tolerance for glucose, easily demonstrable by the test of feeding one hundred grams of glucose and obtaining the blood sugar curve at one-half hour intervals. In the series under discussion Pemberton was able to verify his previous observations, and concludes that diminished sugar tolerance may stand in some relation to inflammatory processes at large. This lowered tolerance seems to be more common than has been appreciated. In view of the demonstrated relation of focal infection to sugar tolerance, "in view of the fre-

D., and Foster, Goodwin L.

quency of foci in arthritis and at large; in view of the frequency of arthritis as a disease and the frequency with which it is accompanied by a lowered sugar tolerance, it seems necessary to modify the view which ascribes to disturbance of thyroid function, next to disease of the pancreas, the most common cause of altered carbohydrate tolerance as measured by this test." This view is not shared by many workers in carbohydrate metabolism. EDITOR.

THE LESION OF RHEUMATIC FEVER

A RECENT article by Jacki[1] calls attention to the specific lesion of acute rheumatic fever. The submiliary myocardial bodies, known as Aschoff bodies, have been found in a large number of cases of recent and old cases of acute rheumatic fever and chorea.

Jacki found these lesions not only in the heart but also in the *galea aponeurotica* of a case in a sixteen year old girl who had had several attacks of chorea and also one attack of acute rheumatic fever. The girl died of heart failure. This is believed to be the second case where Aschoff bodies have also been found in the *galea aponeurotica*.

It is believed that the Aschoff bodies in the heart serve as a differentiation which identifies at autopsy cases of chorea and acute rheumatic fever. It is believed that more knowledge of the etiology of these two diseases will be obtained only when this lesion is used to differentiate acute rheumatic fever from other symptom complexes which often resemble it. W. T.

BACILLI FROM HUMAN TUBERCULOSIS

THIS painstaking work of Griffith[1] gives valuable information about the source of tubercle bacilli in human tuberculosis.

It has been recognized for a number of years that cow's milk, including cream, butter, and cheese, are possible sources of human tuberculosis. We also know that a fairly large percentage of infections occur with bovine types of tubercle bacilli. Much confusion, however, has arisen from the fact that some investigators, evidently on insufficient evidence, have claimed that an overwhelming proportion of all varieties of tuberculosis is caused by the bovine type. This has been considered by them to be especially true in infants and young children. It is believed that to a great extent these opinions have been formed by mental association of milk diet and tuberculosis in children. These opinions are borne out to a certain extent by Griffith's results, but not to the degree usually stated. He analyzed 1,088 cases of tuberculosis, of which 20.7 per cent showed bovine infection.

Further analysis, taken from his tables, gives the following:

Number of Cases	Age Groups	Bovine Infection
221	0 to 5 years	37.55 per cent
312	5 to 10 years	29.45 per cent
150	10 to 16 years	14.66 per cent
384	16 and over	6.25 per cent

It is seen that 37.55 per cent in children in the first age group is the largest proportion of bovine infections found. The rapid falling off of this percentage even by the time ten years of age is reached demonstrates that most cases of adult tuberculosis can not be attributed to the lighting up of a latent tuberculosis acquired in childhood from milk. This is further substantiated by the figures for bone and joint tuberculosis which approximate those for all forms of tuberculosis.

Griffith's article should be read in the original. W. T.

INJECTIONS OF AN ACTIVE DEPOSIT OF RADIUM EMANATION

THIS is evidently the first of a series of studies of this problem.

The "active deposit" of radium emanation in normal salt solution was injected intravenously and subcutaneously in the white rat. This was found to be toxic and above a certain dose resulted in the animal's death in a few days. One of the prominent symptoms was enteritis.

Marked degenerative changes were caused in the liver, cloudy swelling and "erosion" of renal cells in the kidneys, together with hemorrhage and congestion in many other organs. Probably the most important and interesting lesion is destruction of the cells of the bone marrow and replacement by blood. This is of interest since it is known that over exposure of patients to radium results in changes in the blood, such as marked reduction in the lymphocytes. Bagg states that he has investigated the changes in the blood after injections similar to those described in this article and will report on this work later.

It is interesting that only slight changes occurred in the subcutaneous tissue at the site of subcutaneous injections. It is hoped that the effect of intravenous injections of "active deposit" of radium emanations on malignant tumors transplanted into rats will be investigated. W. T.

EPIDEMIC ENCEPHALITIS—A CRITICAL REVIEW

By JAMES M. STANTON, M.D., Washington University Medical School, St. Louis, Mo.

As a result of the appearance of numerous cases of a central nervous system disease of a previously unusual type, which has been variously designated as epidemic encephalitis, lethargic encephalitis, epidemic stupor, and infectious ophthalmoplegia, there has come into existence a considerable mass of literature. This condition immediately became of great interest, both from the point of view of the public and of the medical profession, because of two factors, one the uncommonness of a very frequent sign—the somnolence—the other because of its possible relation to the type of food poisoning known as botulism. At the present moment the interest in the condition is largely narrowed to a consideration of the possible etiologic agent.

Considerable difficulty arises in defining this condition because of the unknown nature of the etiologic agent and because of the variability of the clinical picture. Perhaps the best definition is that of Sainton, as mentioned by Winner,[1] who speaks of it as "a toxic infectious epidemic syndrome characterized clinically by a triad of symptoms consisting of somnolence, palsies of the motor nerves of the eyeball, and a febrile state: and anatomically by a more or less diffuse encephalitis situated chiefly in the gray matter of the midbrain." In addition to the oculomotor paralyses there is frequently a ptosis of some degree and very commonly a mask facies together with generalized spasticity. It is remarkable to what a degree certain of these cases resemble the picture seen in the Parkinson disease.

A Short Historical Note

Buzzard[2] says that there is no reason to assume that this is a new disease. Epidemics of a more or less vague type, but presenting much of the picture of the present one, are reported as having occurred in 1718, 1745, 1768, and in 1802. Crookshank[3] says that Récamier in 1837 observed the apoplectic form of this disease and that Gintrac, of Bordeaux, described in the clearest manner "epidemic stupor" in children. In 1889 and 1890 the disease, "Nona," characterized by somnolence and paralyses of the cranial nerves, appeared in Italy, Hungary, Germany, and France. In Austria, and particularly in Vienna during the winter of 1916-1917, a recrudescence of this disease occurred, and von Economo gave it the name "Encephalitis Lethargica." In 1917 an outbreak occurred in Australia, it being referred to there as the "mysterious disease." Early in 1918 an epidemic of the same condition appeared in France. In the recent epidemic the disease first appeared in England in February, 1918. The English cases were first brought to attention by Harris[4] and Hall[5] with reports of ophthalmoplegia. Bassoe,[6] at a discussion before the Institute of Medicine of Chicago, first mentioned the occurrence of the disease in the United States.

An exact idea of the general prevalence of this disease is difficult to form. There is no necessity of saying that there existed many cases which were never identified as being examples of this condition. In regard to its incidence in the United States there is the added difficulty of the fact that the disease was and is still reportable only in certain localities. That it was quite prevalent is evinced by the report of a number of neurologists who have each individually seen from fifty to one hundred fifty cases. The disease has been relatively widespread in all of the countries in which it has appeared, being not at all confined to the main centers of population. Regarding the seasonal incidence there has been a certain uniformity in ascribing its prevalence as being largely confined to the months between April and October. The months of maximum prevalence of this disease are, therefore, not the months of maximum prevalence of acute poliomyelitis.

From the following tabulation an approximation of the incidence as to sex is arrived at, the proportion of the total cases in this series being 61 per cent males, and 39 per cent females.

A compilation of cases showing the age incidence taken from the reports of McNeal,[7] Hall,[8] Vaidy,[9] Winner,[1] and Hershfield[10] is given.

Age of Patients	Number
Below 1 year	4
1 to 5 years	22
5 to 10 years	17
10 to 20 years	15
20 to 30 years	22
30 to 40 years	14
Above 40 years	37
Total	131

The youngest patient affected was one of the age of four weeks reported by Tilney and Riley;[11] the oldest was a patient seventy-four years old and was reported by Rice-Oxley.[12]

In view of the lack of knowledge of the causative organism of this disease, our ideas regarding its immunity are practically nil. In a study of the major part of the literature of this condition no account was found of any individual having suffered twice from this condition. Information of some possible value might be obtained in regard to the question of immunity, if a series of cases in which the use of serum of cured cases had been tried were at hand. No reports of this method of therapy have been encountered.

Nature of the Organism

At the very onset of the epidemic in England the question as to whether the condition was due to some type of food poisoning, particularly the type known as botulism, was earnestly discussed. In a very short space of time this possibility was disproved, both by the history of the cases and by the inability to find either the specific bacillus or the characteristic lesions produced by this bacillus. The view that the causative factor is of the nature of a food poisoning would seem to be rendered untenable or at least quite unlikely by a case similar to that reported by Batten and Still,[13] in which the disease developed in an infant, entirely breast fed, the mother of the infant being quite well and not having either this disease or influenza.

Whether or not there exists any causal relation between influenza and this disease is extremely difficult to decide. As has been pointed out by Abrahamson,[14] while the incidence of influenza is at its height there seem to be very few cases of lethargic encephalitis that manifest themselves. Likewise, when the encephalitis cases are increasing in frequency there are relatively few cases of influenza. This observation seems to be particularly well borne out as regards the occurrence of cases within the last six months. In Winner's[1] series of forty-one cases, eighteen gave a history of having had influenza. In Hershfield's[10] series of fifteen cases, only three gave a history of influenza. One fact, at least, stands out in reviewing the case reports, and that is that it is far from uncommon to have the patient deny having had any condition that remotely resembles an influenza attack. It should not be lost sight of that the vague complaints of an influenza-like nature that frequently precede by four to seven days the onset of somnolence, or cranial nerve paralyses, may well represent the prodromal symptoms of the disease rather than a preceding influenza.

Far more difficulty is encountered concerning the relationship or lack of relationship between acute poliomyelitis and this "new disease," on which point there seems to be a wide range of opinion. A few hold to the belief that these cases represent, as Crookshank[15] says, "only part of a spectrum of which one end is constituted by 'infantile paralysis' and the other by 'acute delirious mania' and various forms of 'encephalitis'." The report of the British Local Government Board,[16] working in conjunction with the Medical Research Committee, takes a more definite stand in this matter. They state the results of the epidemiological survey were striking "and permitted no ambiguity of inference." Their results show that epidemic encephalitis is not a form of acute poliomyelitis, and that it is a "disease *sui generis* anatomically, and is clinically distinct from analogous affections." It is true, however, that the clinical differences between acute poliomyelitis and this new disease are mainly quantitative rather than qualitative. There is one clinical syndrome of very great frequency which is certainly very rarely seen in poliomyelitis, that is the Parkinson syndrome.

The results of animal experimentation have been contradictory. Flexner is reported by McNeal[7] as having had inconclusive results. Many competent workers have been unable to produce any disease by animal inoculation. The findings of Strauss, Hirschfield[17] and Loewe[18] are of much interest. Their work has tended to show the presence of a filterable virus in the nasopharyngeal mucous membrane of fatal cases of this disease. They report that this virus is capable of produc-

ing, in monkeys and in rabbits, lesions similar to those found in the human brain. Loewe and Strauss[19] reported that they have been able, by the Noguchi method, to grow an organism from cases of this disease. Their organism resembles that described by Flexner and Noguchi in poliomyelitis. The injection of their organism into animals causes lesions similar to those seen in man.

Modes of Conveyance

A very clear working idea of the modes of conveyance of this disease and of the factors controlling its clinical occurrence is given by Lieut. Col. James,[20] who states "encephalitis lethargica is one of a group of diseases in which, as in cerebrospinal fever and acute poliomyelitis, the pathogenic organism is much more generally present than the clinical evidence implies. Cerebrospinal fever arises in one of two ways: (1) as a result of a breakdown in the immunity to the effects of the virus which the individual who harbored it had up to that time enjoyed; (2) as the result of a non-immune person becoming infected with a strain of the virus which has attained the degree of pathogenic action described as specific. During severe epidemics . . . cases of cerebrospinal fever are arising in both these ways, but during inter-epidemic and mild epidemic periods it is seldom or never possible to obtain evidence that the illness is infectious. At such times cases of the disease are always scattered sporadically and they cannot be traced to any known source of infection, except the patient himself. This is the view that best explains the irregular widespread, sporadic distribution of encephalitis lethargica." It would therefore seem that the presence of the disease represents a breakdown of personal immunity, due to one or both of the following factors: increased virulence of the organisms, or lowered resistance of the tissues affected.

Very few observations are on record of a person who has been in contact with a definite case of this disease developing it. Schnoor[21] mentions the case of a physician developing the disease about four weeks after being in attendance upon a patient suffering with it.

Gross Changes.—During life the brains of a number of these cases have been seen. This is particularly so with Buzzard's[2] series of cases. A number of his cases developed signs of increased intracranial pressure and were subjected to a decompression operation. At operation there was seen a marked meningeal and cortical hyperemia, together with a very definite thrombosis of certain of the cortical vessels. The accounts of the postmortem macroscopic findings are somewhat at variance, especially concerning involvement or lack of involvement of the cortex and meninges. The findings upon section are well described by Mott,[22] who, in speaking of the work of Marienesco, says that disseminated miliary hemorrhages were seen in the region of the floor of the fourth ventricle, the aqueduct of Sylvius and even about the third ventricle, as well as in the posterior parts of the pons and peduncles. Of the cortex he says that except for some congestion of the vessels of the leptomeninges there are no macroscopic or microscopic lesions. It is of interest to recall that the region of maximum density of the hemorrhages in these cases is the region that has long been recognized as being especially vulnerable to toxic and bacterial agents, as, for example, in the hemorrhagic polioencephalitis of Wernicke. Not infrequently there are no pathologic findings upon examination in the gross.

Microscopic Changes.—Bassoe and Hassin[23] noted in their examinations that the pia appeared infiltrated and frequently showed distended meshes containing hyperemic vessels, these changes indicating a mild leptomeningitis. The chief features of the microscopic pathology as summarized by Buzzard[2] are: (1) Perivascular infiltration mainly with small, round cells. (2) Small capillary hemorrhages which suggest a gradual oozing of blood through the damaged walls of small veins and capillaries. (3) Thrombosis of small and middle size vessels in different stages of organization. (4) Ischemic softenings presenting the appearance of the hemorrhagic infarctions which are seen in other organs. (5) Subarachnoid hemorrhages and cellular infiltrations of the leptomeninges. (6) General neurogliar proliferation. (7) Changes in nerve cells, in some places showing chromatolysis and in others a process resembling that of coagulation necrosis.

According to Bassoe and Hassin, these piaarachnoid changes are well marked and occur about every part of the brain, being particularly well marked about the base of the cerebellum and not infrequently involving the contiguous parenchyma. Besides the perivascular infiltrations there are other very evident changes in the cortex, chiefly of the nature of satellitosis, chromatolysis, and neuronophagia. The cortical archi-

26. Von Economo, C.: Encephalitis Lethargica, Wien. klin. Wchnschr. 1918, xxxi, 850.

tectonic system remains practically unaltered. The subcortical fibers remain likewise unaffected. The case of Calhoun[24] showed definite spinal cord changes of the nature of an acute diffuse infiltrative myelitis, associated with a thickening and infiltration of the pia-arachnoid. The cord changes found by her bore a definite relation to the vessels.

There is a certain conformity of opinion regarding the absence of new vessel formation. Epitheloid cells, of either vascular or glial origin, are infrequently seen. The type and variety of infiltrative cell varies. Calhoun speaks of the slight vascular infiltration of the vessel walls and the presence of masses of homogeneous bodies such as were previously reported in cases of the trypanosomal sleeping sickness. Bassoe and Hassin mention lymphocytes, plasma cells, polyblasts, fibroblasts, and rod cells. Marienesco[25] reports the presence of plasma cells and some lymphocytes. Von Economo[26] mentions the adventitial sheaths as being crowded with lymphocytes, leukocytes, and plasma cells.

Uniformity of nerve cell change is present to a marked degree throughout the brain and spinal cord. Chromatolysis and the axonal reaction are found in the ganglion cells. Satellitosis is also usually marked. Marienesco mentions changes in the cerebellar Purkinje cells like those seen in fatigue. A well defined proliferation of the ependymal cells about the central canal of the cord, together with some associated glial reaction, has been a rather uniform finding. All attempts to find organisms within the central nervous system of these cases, by staining methods, have been fruitless.

The Symptoms Noted

The period of incubation is unknown. As a rule the symptoms come on insidiously and it is impossible definitely to fix the time of onset. However, in a certain few cases there is an acute onset, usually with either apoplectic or psychotic manifestations. These last are among the unusual types, however. More frequently there is at the onset a vague feeling of lassitude, vague pains over the body, headache, and inaptitude for work. This indefinite combination of symptoms, especially if occurring at a time when influenza is epidemic, frequently results in the condition being called "influenza." At or about this time, or even after a few days' interval of seeming return to normal health, the lassitude becomes more marked, and the patient's condition is better expressed as lethargic, suporous or somnolent.

These terms represent the facial aspect of the disease, rather than an expression of the actual intellectual potentialities of the patient. It would seem that this facies is the result of an actual partial facial nerve paralysis, together with a third nerve paralysis of varying degree. It may perhaps represent instead a bilateral facial spasticity. There usually develops at this stage, more or less rapidly, various cranial nerve paralyses. The cranial nerves most frequently affected are the oculomotor nerves (third, fourth, and sixth), the seventh, and the twelfth. There may be, and it is not unusual to find, singly or together, many of the cranial nerves involved. Not infrequently there is complaint of headache of varying degree of intensity. An increase of temperature to, usually, 100° to 103° now appears. The pulse is usually in proportion. Occasionally the pyrexia is more marked, and may even reach 106° or higher. Delirium is not infrequent, especially as a nocturnal manifestation.

These seem to be two or more distinct courses that the disease may now take. Cases of the first or acute type grow rapidly worse and terminate fatally usually at the end of the second or early in the third week. The cases of the other type, the subacute or chronic, run a much slower course, having commonly a duration of eight or ten weeks and not infrequently lasting three or four months.

The blood has been carefully investigated by Vaidya,[9] who in a series of eighteen cases found the leukocyte count to vary between 3,600 and 14,000, the average count being about 8,400. Hershfield, in a series of eleven cases, found an average count of 14,000 leukocytes. There are usually no profound changes in either red cells or hemoglobin, although during convalescence there is not infrequently an anemia of some degree.

Examination of the cerebrospinal fluid has shown no constant picture. A moderate number of these cases have shown a normal fluid. Whether a normal fluid exists throughout the entire course of certain of these cases is difficult to say, but it would not seem unlikely. The greater part of the cases show on puncture a fluid under somewhat increased pressure. The cell count is ordinarily between fifteen and fifty, and mononuclear cells usually predominate. Tests for protein increase are usually positive. The Wassermann test, on uncomplicated cases, is negative. The colloidal gold test has given widely varying results. Some of the cases have shown a typical paretic type of reaction. More commonly the curve is of the midzone, so-called luetic, type. There has been a certain uniformity in the inability to find organisms in the fluid.

The pulse presents no special character. It is increased in rapidity, usually in proportion to the height of the fever. The blood pressure usually

shows no marked change. In one of my cases it rapidly rose, during a period of four days, from 120 to 180 mm., being lowered on two occasions from twenty to thirty points by lumbar puncture. This was associated with an increasing optic neuritis and was looked upon as a manifestation due to increasing intracranial pressure.

A number of these cases have developed skin eruptions. Schnoor reports a case with a miliarial eruption. Buzzard[27] mentions a case with a papular rash over the forearms, buttocks, and legs; another with a rash like that of scarlet fever; and still another with morbilliform rash over the chest, abdomen, and arms. A very common and annoying symptom in many of these cases has been recurrent drenching sweats. Drooling has also not been infrequent. Retention of urine has been met with repeatedly.

Morbid Anatomy

Of the signs or symptoms referable to the olfactory nerve little or no mention is made. Of the optic nerve, some diminution of vision has been noted. Perimetric studies have not been made on many of these cases. Fundus changes of the nature of an optic neuritis, and even amounting to a choked disc, have been found not infrequently. The third, fourth, and sixth nerves have been the most frequently and uniformly affected. Their affection in the form of a diplopia has been noted by a predominating majority of the patients. The particular muscle or combination of muscles affected has varied. In some of the cases there has been a complete *ophthalmoplegia externa*. Ptosis, either unilateral or bilateral, has been rather uniform. In general it may be said that this ptosis has been of the partial rather than of the complete type. Pupillary irregularity, less frequently an inequality, has been noted in about 25 per cent of the cases. The reaction to light has been uniformly non-affected. The reaction to accommodation is frequently poor. Nystagmus of the horizontal type has been observed very frequently.

Involvement of the fifth nerve, either in its motor or sensory portion, has been distinctly uncommon. Abnormalities of the facial innervation, in the form of the Parkinsonian facies have been extremely common, in fact this symptom has shown itself in almost all of the cases. Well marked and typical cases of facial paralyses have been observed in some series with a frequency of almost one in five. Deafness of rapid onset has been encountered but infrequently. Vertigo, particularly tinnitus, has been more common.

Paralyses of the palate and of the vocal cords have been infrequently seen. Speech disturbance of the nature of dysarthria has been fairly common. Inability to protrude the tongue, and difficulty or inability to swallow have been frequently annoying features. There has been little evidence of vagus involvement either by paralysis of the larynx or by cardiac disturbance.

Among the common features of an involvement of the motor system we find the more or less generalized spasticity which occurs in practically all cases at some stages of the disease. Isolated paralyses of the different limbs have been mentioned not infrequently in the various case reports. These paralyses are usually associated with increased tendon reflexes and with the pathologic toe sign indicative of a pyramidal tract lesion. In some of these cases pain upon passive motion of the spastic limbs is very marked. Evidence of extra-pyramidal tract involvement is not infrequent. As evidence of this are the various complete and incomplete Parkinsonian syndromes. Howe[28] reports a case showing the picture of the thalamic syndrome. Tremors of various kinds, particularly of the fine, moderately rapid, non-intentional type, have been frequent.

Certain of these cases, particularly at the time of onset, have presented the picture of a meningitis, showing marked cervical rigidity, together with the Kernig sign. Ankle clonus with no definite sign of paralysis has been met with now and then. Various sensory disturbances have been found associated with this disease. These sensory signs are usually associated with more or less mild paralyses of the flaccid variety. These changes are to be looked upon as the expression of a peripheral neuritis which may be either toxic or infectious in nature. These peripheral neuritides are frequently confined to but a single nerve, as, for example, a unilateral ulnar neuritis.

The Presence of Complications

Fortunately, the greater proportion of these cases go on to recovery without any complication or residual symptoms developing. Hemorrhage into the vitreous has been reported a few times. A not infrequent and very distressing thing has been the late development of involuntary movements affecting the extremities, tongue, etc. These movements usually show a tendency to clear. Various mental conditions, such as a depressed state, apathy, and indifference to the surroundings, have not been unusual. A post-encephalitic amentia seems to have been of rather infrequent occurrence. There is little mention of epileptic seizures amongst the sequelae of this condition, although they are not infrequent during the acute stage of the disease. Among the fatal cases, terminal conditions of pneumonia or of speticemia are, as a

28. Howe, H. S.: The Thalmic Syndrome in Encephalitis Lethargica, Neurol. Bull., 1919, ii, 190.

matter of course, very frequently encountered.

Cases of this disease appear in many different forms. In general they may be grouped from one of two standpoints, one from the standpoint of the clinical picture produced, the other from the standpoint of localization of the point of maximum severity of the process within the nervous system. Tilney and Riley[11] have proposed a useful grouping from the symptomatic standpoint. They have recognized the following types: (1) The lethargic type. (2) The cataleptic type. (3) The paralysis agitans type. (4) The polioencephalitic type. (5) The anterior poliomyelitic type. (6) The posterior poliomyelitic type. (7) The epilepto-maniacal type. (8) The acute psychotic type.

A ninth form, the infantile type, has been tentatively proposed by these authors. This grouping, while not permitting of an accurate classification of all cases met with, yet proves useful from the prognostic and other standpoints.

Points in Diagnosis

Several points are to be borne in mind: (1) Errors in diagnosis are inevitable, even under the most favorable conditions. (2) Spinal fluid examination is scarcely to be dispensed with. (3) This disease is extraordinarily variable in its manifestations. (4) Diagnosis must be made chiefly by exclusion. Perplexity in diagnosis arises chiefly in connection with the following diseases:

Tuberculous meningitis.—The marked pleocytosis of the spinal fluid, together with the presence of the tubercle bacillus, and the characteristic sulphosalicylic acid—mercuric chlorid precipitation ratio characteristic of this disease, can be made use of.

Cerebrospinal meningitis.—The presence here of the organism with its characteristic precipitin reaction should prove of ample value.

Cerebrospinal syphilis.—This probably will, in certain instances, offer the greatest difficulty of exclusion. The presence of a positive Wassermann reaction, together with the history, should be of particular value. A therapeutic test may prove of value at times.

Intracranial new growth.—For differentiation here one will have to depend upon the course of the disease, the presence of choked disc, other evidence of increased intracranial pressure, roentgenographic findings, localizing signs, and perhaps even upon an exploratory operation.

Hysteria.—This has frequently been the early diagnosis made in these cases. The presence of a history of previous hysterical manifestations, the presence of marked sensory disorders which are of a functional type, and the absence of any of the definite signs of organic nervous system will prove of value.

These in general are the diseases which one has most frequently to consider in dealing with a supposed case of epidemic encephalitis. It should be emphasized again that errors in diagnosis are inevitable in dealing with this disease.

Factors Affecting Prognosis

Concerning the outcome, perhaps nothing better can be said than to repeat the dictum of Buzzard:[2] "At present we can only say that some cases recover completely, others survive the acute stage but carry with them in after life permanent defects due to the morbid process, while a certain number die either from toxemia or hemorrhage in the acute illness or from some complication following it."

The exact mortality rate varies considerably. Winner reports the French rate at about 35 per cent, the English rate at about 25 per cent, and the Australian rate about 5 per cent. The mortality rate in the United States is very difficult to estimate. The figures at hand show a mortality of nearly 25 per cent, but this rate can obviously not be applied to the cases in general, because (1) the mild cases do not come to attention, and (2) there is no doubt a high percentage of inaccurate diagnosis. Probably 15 per cent would serve roughly to indicate the degree of mortality. It is especially the epilepto-maniacal and the acute psychotic types, together with those cases in which the burden of the affection falls upon the lower cranial nuclei and the respiratory center, which have the worst prognosis.

Details of Treatment

There are no specific measures at present at our command for the treatment of these cases. During the acute stages the patient should be kept in bed and some degree of isolation enforced. The treatment is essentially symptomatic. For the pyrexia, when it becomes marked, hydrotherapeutic measures are of the most value. The elimination should be carefully watched. In general it would seem wise to force fluids. Feeding should be frequent and in small quantities. At the first sign of difficulty in swallowing, nasal feeding should be resorted to. While this is being carried on a careful watch should be kept for signs of a developing acidosis.

Repeated lumbar punctures are perhaps useful, especially if there is evidence of cerebral edema. The symptomatology of this disease is so varied that it is obviously not possible to touch upon the more specific symptoms.

THE TUBED FLAP IN SKIN GRAFTING

THIS method was presented by Maj. H. D. Gillies,[1] R.A.M.C., at a meeting of the Clinical Congress of Surgeons in New York last fall. It has been tried out especially at Sidcup, England.

This device makes the skin of practically every part of the body available for repair work where it may be needed. The blood supply of the flap is well taken care of while the new circulation is being established. There are no raw surfaces as in the usual pedicle method, therefore the danger of infection is reduced.

The tubed pedicle flop in repair of facial burns. (Photograph by courtesy of Surgery, Gynecology and Obstetrics.)

These tubed pedicle flaps are prepared by making two parallel incisions about two inches apart, starting from the angle of the jaw or upper part of neck for a plastic on the face, and extending downward over the chest or back. These incisions are made through the skin down to the fascia. The strip thus formed is raised. Bleeding points are caught and ligated. The cut edges of the strip are then united with a fine silk suture in such a way that a tube is formed with the skin outside. The edges of the adjacent skin are undermined and brought together with tension sutures. Occasionally it may be necessary to use a Thiersch graft to close this secondary wound. Thus a tube is formed running from the angle of the jaw to the chest or back. The angle of the jaw is chosen as a base because of the vascularity of this region. About two weeks later at the lower end of the tube the flap which is ultimately to be transplanted is outlined by an incision extending down to the fascia. The bleeding points are ligated. This is done to shut off the circulation from the adjacent skin and to stimulate the formation of an increased blood supply coming through the tube.

About three weeks after the tube has been constructed and when healing is complete the outlined flap is raised and transplanted to its new position and sutured in place. The blood supply is taken care of through the tube. The progress of the new circulation in the transplanted flap can readily be tested by pinching the tube pedicle and then pressing on the flap and noting how soon the color returns after the pressure is released. When the flap is thoroughly healed and the new circulation well established, the pedicle is amputated.

The pedicle can be excised completely, can be "untubed" and returned to its original site, or can be used again either as a pedicle for a new flap which can be cut from its former base, or as a graft itself. If used as a graft it must be opened, the scar excised, and the central core of fibrous tissue which often forms must be removed. It can now be swung as a flap over the nose, or used as a new upper or lower lip. When used as a lip, it may be better not to "untube" it, but to use it as a flap with skin on both sides.

The caterpillar tubed flap is a tubed pedicle flap used when it is necessary to bring skin from a distant point. The flap is prepared as above described and is then planted close to the base of the tube. After healing, the former base of the tube is moved towards the area where the flap is wanted and, later, the flap is again moved up close to the new base. Thus by a series of implanta-

tions and re-implantations the skin flap is brought to the place where needed, the process resembling closely the movements of a caterpillar.

Major Gillies calls attention to some of the fascinating possibilities of the tube flap in the future, its use for the reconstruction of the penis, of a breast, or, with the skin inverted, as an artificial esophagus.

Points Regarding Technic of the Wolf and Thiersch Grafts.—The Wolf graft is best used over firm surfaces, such as the forehead and the bridge of the nose. The graft should be cut the exact size and shape needed. According to Gillies, it is wrong to cut it large and "allow for shrinkage."

The graft, when sutured into place, must be evently stretched and should be as taut as the surrounding skin. Pressure is applied over the graft by means of bandages or molds. The graft is pressed against the underlying tissue throughout the whole extent, thus preventing accumulations of blood or serum. The pressure is kept up from three to five days.

The Thiersch[1 2 3] grafts must also be kept in apposition to the granulating tissue. An expedient way of doing this is to make a mold of the area to be grafted out of dental composition. The grafts are laid over this mold with the raw surfaces uppermost. The mold is then pressed into place and firmly held for a week or ten days. When the mold is removed, the grafts will be adherent.

STANDARDIZED SURGICAL METHODS IN INDUSTRY*

By C. D. SELBY, M.D., Toledo, Ohio

THIS conference is called in response to the impression, which is frequently met with among industrial physicians, that standard methods of surgical procedure are desirable in industrial dispensary practices. The objects of this conference are to determine (1) if such standards are desirable; if so, (2) of what shall they consist; and (3) what is the best means for securing their general adoption.

INDUSTRIAL MEDICAL SCIENCE

The primary motive of any association arises from the need of mutual suggestion, support, and the solidarity which results from common group interests.

Industrial physicians have come together to solve their mutual problems and industrial medicine has reached a period of organization which selects and disseminates the best practices of their best men.

It is through such discrimination and through cooperative research that industrial medicine will evolve as a science whose principles are so well defined as to form a guide in the specialty and a gauge of the quality of service it delivers.

All of us who are engaged in industrial practice, sooner or later and consciously or not, come to follow certain methods of procedure. We get into the habit of using a certain antiseptic or some one particular local application. We favor a special kind of dressing table. We prefer to have our equipment arranged in a certain way. In other words, we standardize.

This is apparently the expression of a natural inclination to form habits, which is a human tendency. Although industrial physicians, we are quite human in this respect. Some of us fall into habits of procedure, some of us imitate the methods of others, and a few devise their own after observation and study.

This last mentioned type are the leaders in industrial medicine and surgery and are known to us all; they have created the only standards that exist. The majority of us are of the second type; we are the imitators, and through our imitation of the examples set by the leaders has come the progress of industrial medicine to the position it now occupies.

In considering the essentiality of standards, these two points are then of prime importance: (1) We are creatures of habit, and in our practice of industrial medicine our natural inclination is to standardize. (2) The majority of us are imitators, and if we do not have good standards held up as examples for us to follow we will accept others of less merit.

It may possibly be said that standards are expressions of exactness, that industrial medicine is not yet an exact science and is therefore incapable of standardization. Nevertheless, there are certain methods and means that have become sufficiently widespread in their adoption to warrant their being set up as minimum standards and used as the framework for the building up of a more exact science. Experience will suggest

*This article has been prepared for the purpose of suggesting lines of thought and for arousing discussion in a round table conference held during the annual meeting of the American Association of Industrial Physicians and Surgeons at New Orleans, April 26 and 27, 1920.

additions to and modifications of these standards from time to time, and thus the science will grow in exactness. The formulation of standards would therefore seem desirable.

(At this point the subject was opened for general discussion, and remarks were limited to the question, are standards of surgical methods desirable in industrial practice?

Standards of Minor Wound Treatment

To attempt to standardize the whole field of industrial surgery at one sitting of this conference would be quite impossible; the field is altogether too broad. Inasmuch as the minor injury is the most evident reason for the employment of industrial physicians, it seems appropriate that standards of minor wound treatment should receive first consideration. As a matter of fact, if the conference succeeds in devising standards of minor wound treatment in the short time allotted to it, a meritorious work will have been accomplished.

The following standards are presented, without argument, as a basis for discussion:

Fresh Wound

1. Remove devitalized tissue.
2. Cleanse with ether.
3. Spray or swab wound with iodin (2 per cent).
4. If cavities exist, pack them with dry gauze.
5. Dress dry.

Infected Wound

Treat all wounds as though infected the second, third and fourth days after injury is received.

1. Remove all scabs and loose skin.
2. Cleanse with ether.
3. Spray or swab with Dakin's solution of sodium hypochlorite.
4. If cavities exist, pack them with gauze saturated with Dakin's solution.
5. Dress moist.

Clean Wound

Treat all wounds as clean on the fifth day and after unless infected.

1. Spray or swab with neutral hydrocarbon oil containing iodin.
2. If cavities exist, pack them with dry gauze.
3. Dress dry.

Indolent Wound

1. Cleanse with ether.
2. Spray or swab with argyrol (5 per cent solution) or swab with balsam of Peru.
3. If cavities exist, pack them with dry gauze.
4. Dress dry, using slight pressure.

Burns

1. Apply hydrocarbon salve and dress dry.
2. This may later be varied with neutral hydrocarbon oil containing iodin.
3. Or treated as an indolent wound.

(At this point the standards of minor wound treatment were subjected to discussion.)

Standards of Equipment for Minor Wound Treatment

The equipment and materials used in the treatment of minor wounds are usually placed upon a dressing table where they may be easily reached by the physician or attendant. The following is a list of equipment and materials. It is offered, without comment, as a basis for discussion:

1. One five by six-inch white enameled jar containing 1-inch bandages.
2. One five by six-inch white enameled jar containing 2-inch bandages.
3. One five by six-inch white enameled jar containing sterile gauze.
4. One five by six-inch white enameled jar containing sterile cotton.
5. One five by six-inch white enameled jar containing sterile wooden tongue blades used as spatulas for the application of an ointment and applicators dipped with cotton swabs.
6. One three by four-inch white enameled jar containing a neutral hydrocarbon ointment.
7. One two by one-inch covered glass dish containing sterilized rubber tissue cut into strips for drainage purposes.
8. One four by seventeen-inch white enameled tray containing six splinter forceps, six sharp pointed scissors and six probes, all sterilized.
9. One medicine glass, containing a 5 per cent solution of carbolic acid, in which is kept a forceps for the removal of sterile instruments from the previously named tray.
10. One three by eight-inch white enameled tray in which are discarded used instruments and from which they are gathered from time to time for sterilization.
11. One hard rubber atomizer containing a 2 per cent solution of iodin.
12. One ordinary atomizer containing Dakin's solution, made fresh daily.
13. One atomizer containing a solution of iodin in hydrocarbon oil.
14. One atomizer containing benzin.
15. One can of ether.
16. One jar of solidified liniment.
17. Several one-fourth-inch strips of adhesive plaster one inch long.
18. One bandage shears.
19. A number of aluminum finger guards. These are very useful; they enable workmen who have lacerated finger tips to continue at work with a great deal more comfort than if unguarded.

(At this point the discussion on the standards of equipment for minor wound treatment was opened.)

There is a growing tendency in dispensary practice to group all of the furniture, fixtures, equipment, and materials essential to the treatment of minor wounds, the group being called a unit,—the minor dressing unit. The materials and equipment that might be regarded as essential to this unit have already been mentioned. The furniture

and the fixtures will now be offered for discussion and, as in the presentation of the others, without comment, except that as far as possible all should be finished in white.

1. One dressing table, twenty-one by forty-three inches in its top dimensions.
2. One stationary wash bowl.
3. One waste receptacle.
4. Chairs or stools for the patient and the physician.
5. One foot rest.
6. One arm rest.
7. One movable lamp with a flexible neck.

(The standards of the minor dressing unit were here opened for discussion.)

Means for Securing Adoption of Standards

The American Association of Industrial Physicians and Surgeons is the leading association in this field of practice. Its position of prominence confers upon it a very definite obligation, the obligation of leadership. It should endeavor at all times to enhance the knowledge peculiar to the field and provide means for the dissemination of that knowledge among the members. It should strive unceasingly to improve the ability of industrial physicians along practical lines.

The fixing of standards is a step in this direction; but to adopt standards without attempting to provide a means for their utilization would be futile. The great question before this conference is, then, how can a widespread adoption of standards be secured?

It is necessary first, however, that the Association determine that the standards it adopts are representative of the majority of opinion among its members and acceptable to them. This Conference does not have authority to do this; its authority does not extend beyond discussion of the matters that have already been brought before it. It can, however, consider ways and means for securing the official action of the Association. It can, for instance, recommend by resolution that the board of directors take such steps as may be necessary to formulate standards which will represent the majority of opinion.

(Discussion opened at this point.)

This Conference can recommend further, also by resolution, that the Association take some official action designed to secure the general adoption by its members of the standards as formulated. It can suggest, for instance, that adoption of the standards be made a requisite of membership; that is to say, no industrial physician can become a member until he shall have agreed to follow the standards of the Association. He should agree further not to modify the standards until the changes he may have in mind shall have been submitted to the Association for approval, together with his supporting arguments.

There may be disadvantages to this plan, but on the whole it would have the very decided advantage of (1) providing the members with good examples to follow in their practice, and of (2) providing a basis for study and a foundation for the development of industrial medicine as a science.[1]

VISUAL LOSSES OF ONE EYE

A standard for the estimation of compensation for partial or complete loss of vision is an unaccomplished necessity, says Dr. Frank Allport in the *Journal of the American Medical Association* of January 17, 1920. Such a table cannot be invariably equitable, but it would be a steadying foundation for judicial consideration. Ocular damages should be estimated on conditions prevailing at the time of litigation. Visual conditions should be estimated with glasses except after cataract operations. Snellen's test types Allport regards as erroneous and misleading as they were intended merely to serve as an international language interpreting ocular refraction and not to indicate visual insufficiencies.

Allport considers an individual industrially blind whose vision is insufficient for ordinary work. An answer to the question of what constitutes industrial blindness was arrived at by the Chicago Ophthalmological Society after consulting with many ophthalmologists, lawyers, industrial commissioners, and insurance managers, accepting that vision worse than 20/200 constitutes industrial blindness. On the basis of vision worse than 20/200 representing industrial blindness, or 100 per cent loss of vision, the Chicago Ophthalmological Society has graded down the percentages and compensations in the accompanying table.

Vision	Visual Efficiency Per Cent	Loss of Vision Per Cent
20/20	100	0.0
20/30	94.5	5.5
20/40	89.0	11.0
20/50	83.5	16.5
20/60	78.0	22.0
20/70	72.5	27.5
20/80	67.0	33.0
20/90	61.5	38.5
20/100	56.0	44.0
20/110	50.0	50.0
20/120	41.0	59.0
20/130	36.5	63.5
20/140	32.0	68.0
20/150	28.5	71.5
20/160	23.0	77.0
20/170	18.5	81.5
20/180	14.0	86.0
20/190	12.0	88.0
20/200	10.0	90.0

In closing the discussion of the desirability of arriving at standards of compensation equitable both to employee and employer it is suggested that, owing to the frequency of claims for personal injury, for ocular damage and all other accidents as well, perfunctory examinations should be discountenanced, and skillful examination should disclose the physical condition of employees before they are assigned to work.

1. Editor's Note:—As a result of the discussion following the reading of this paper a committee was appointed to make a study of the subject and report at the next annual meeting of the Association.

THE NECESSITY FOR AN INSTITUTE OF INDUSTRIAL HYGIENE

By CHARLES BASKERVILLE, Ph.D., F.C.S.; Professor of Chemistry and Director of Laboratories of the College of the City of New York; and Chairman of the Committee on Occupational Diseases in the Chemical Trades of the American Chemical Society, New York City.

THE universal publicity given to the use of "poison gas" in the World War undoubtedly directed greater attention in the United States to chemistry, with its mysterious possibilities, and the chemical industry, with its opportunities for production of wealth and possible control of trade therewith, than any other agency in modern time. Germany's specialization in the manufacture of coal tar derivatives coupled with extensive propaganda created an erroneous impression of the non-existence of a pre-war chemical industry in the United States. There is no necessity now to contradict the false impression, but it is a fact that the war brought about a remarkable stimulation to American chemical industry.

Speed Factor Lessens Safety

The pressure drove existent plants to intense systems for super-production. The exigency of the emergency brought about the hasty construction of many plants for the production of chemicals of great variety needed in the prosecution of the war. The speed factor did not admit providing all the preventives for the protection of the workers in some instances and the transitory character of contracts in others caused little concern for the welfare of labor. Chemicals have received most of the blame and unusual attention has thus become directed to industrial hygiene.

These and other factors associated with the enormous and permanent development of the chemical industry have caused thinking chemists to give the subject most serious consideration, often expressing a strong hope that something worth while might be done in a large constructive way to better conditions of the labor of the industry, the direction of the activity and the standard adopted to be based upon adequate preliminary study.

TO FOSTER CHEMICAL RESEARCH

Progress in chemical industries must of necessity carry with it a parallel improvement in the hygienic conditions of chemical workers, where the relation of disease to occupation has been established.

It should not, however, be necessary for each separate industry to discover right conditions for their men, for trial and error in this field cost in health and human welfare.

An endowment must be found to sponsor the coordination of all research agencies in chemistry, for the compilation of all data to present achievement, and for the direction of future activities.

Something has been done by individual corporations, National, State and Municipal public health boards, and by social welfare and other organizations, but the efforts of these agencies have not been coordinated. Prior to the war the American Chemical Society, through initiation by the New York Section, organized a Committee on Occupational Diseases in the Chemical Trades. The author has been chairman of this Committee since its formation and has attended numerous meetings seeking to do something of value, (1) through developing the interest of the manufacturers, (2) cooperation on obtaining uniform legislation in the different states and municipalities, and (3) bringing about a limited degree of publicity mainly among chemists. Some thing has been done in the way of research, in legislation, and publicity. In the first we have stimulated various health agencies to study conditions in the main and cooperated with representatives of boards of health and bureaus of labor in their investigations. In the second we have cooperated in formulating some uniform laws for a number of states and cities, especially in connection with wood (methyl) alcohol, now to be called correctly, methanol. In the third we have secured important contributions from specialists and caused them to have wide distribution in the trade.

The work has not been systematic or organized for the very good reason that it has had no financial support. The author knows that he may secure contributions for the work, but he feels that now is the time when it should be undertaken, according to a large program which would call for the entire time of a competent man and for more money than he could hope to secure. The program would call for the cooperation of the chemist, but not his direction. It calls for broad and comprehensive special training in the field of

preventive medicine, which involves social welfare.

The mephitic odor of the laboratory covers a maze of mystery in the lay mind and is held responsible for numerous maladies. The word "chemical" is sinister. Where chemical processes are in operation, especially when fumes or vapors, even though the latter be only steam, are seen to escape from the works, there grows a feeling of suspicion—often with reason—and all kinds of sickness are attributed to these "poisonous substances." If the author may judge from numerous letters, even the members of the medical profession are not free from these sensations and confessions. And well they may be in many instances for, even though the action of many chemicals in varying degrees of concentration be known, of many more the insidious effects are absolutely closed books. They require most diligent study and painstaking research.

In this connection it may be stated that there is an urgent need for publication of an immense amount of valuable research carried on by the Chemical Warfare Service of the Army and Navy, which now appears to have little chance to reach the light of day. The data on the physiological factors and changes involved in fatigue are of immense value. The alterations in gas masks for use in chemical industries in peace times constitute an important problem. The fact that workers, soldiers, and civilians, in chlorine plants or where small amounts of chlorine permeate the air, were practically immune to influenza during the first epidemic, while their neighbors living and working under similar conditions, save the chlorin, were stricken right and left, opens a vista comparable to the hopeful days of the Pneumatic Institute out of which came inhalation anesthesia, gaseous disinfection, and foundational knowledge of bacterial changes.

There are good people in the chemical industries and there are far sighted corporations seeking means to improve conditions, but the evils of the conditions first serve to call attention to their existence. Efforts to palliate are evident in providing medical attention. It is good business to have healthy labor, but the motive is primarily humanitarian. Multiplication and adaptation of education for the workers call for teachers with qualifications peculiar to the needs.

An excellent, but limited, program of training given at a few institutions is available for those who seek, but we know that suitably trained men and women cannot be had in adequate numbers to meet the demands.

I speak without authority, but I assert with assurance, that the chemical industry will welcome and cooperate with the separated efforts for the improvement of conditions; but it will go much further if those efforts are coordinated. So I venture to say that it would appear desirable to extend the present localized opportunities for instruction and tie them together in one main institute for research, advanced and special instruction, and for coordination.

Such a program is one that should appeal to one of the endowed foundations. It is one that a foundation would be capable of handling and able to inaugurate at once. Numerous currents, cross, converging, or diverging, have served to delay action. Data and ideas, differing in not irreconcilable modes of operation only, have been marshaled in such impressive array that other agencies may arise to provide the ways and means; but when? It has been strongly stated that such a project should be handled through the Federal Government and its agencies. That spells delay, as all men of common sense know too well, and the best promise of its being undertaken would seem to lie in the direction of one of the great foundations.

DURATION OF WAGE EARNERS' DISABILITIES

A tabulation of studies representing the experience of the Workmen's Sick and Death Benefit fund, presented by Boris Emmet in the March *Labor Review*, shows that slightly over 19 per cent of all cases and about 3 per cent of the total days lost were due to disability of less than one week. In 7.4 per cent of cases the disability lasted twelve weeks and over, these cases representing 37.3 per cent of all the disability days.

The age factor is to be considered in the duration of disability. The proportion of cases lasting under one week was 26.5 per cent in the age group 25 to 29, less than one-half of that rate—12.5 per cent—occurring in the age groups of 55 to 59. The percentage of disabilities lasting twenty-five weeks and over shows 1.4 per cent in the age group 25 to 29 as compared with 3.3 per cent in the age group 55 to 59. The proportion of cases lasting twenty-five weeks and over is 300 per cent greater in group 60 to 69 than in group 20 to 29.

The article is of great value to organizations having or proposing to have employees' sick benefit societies. The two principal factors to be considered are age, which is the most important, and occupation. Deductions are made from tables which give all occupational experience for specific and identical age groups, so as to eliminate the age factor and to ascertain the exact influence of occupation on the disability duration.

MORE PAY FOR INJURIES

Injuries reported to the United States Employees Compensation Commission since its organization in 1916 have numbered 61,628. Disability claims granted in the last three years number 29,866, the deaths, for which payments have been made, totalling 1,095. In 28,256 cases of temporary disability the average duration was seventeen days; in 15,374 of these cases which were compensated, the average duration was twenty-five days, resulting in an average award of compensation of $40.06.

THE SERVICE DEPARTMENTS OF THE R. K. LEBLOND MACHINE TOOL COMPANY

By SANDFORD DeHART, Director of Hospital, Cincinnati, O.

THE Social Service Department and the Hospital Department of this plant are two separate divisions, presided over by two separate directors.

The hospital department is under the supervision of a hospital director, and the social service department is under the supervision of a welfare director. These departments hold daily consultations with reference to the mental, physical, and general welfare, or the relief of the men in the shop.

The hospital department consists of nine rooms, a waiting room, a first aid room, a bacteriological laboratory, an operating room, an office, a dental room, a dark room for eye work, a bedroom, and a sterilizing room.

The hospital has been organized with two aims in view: (1) to take care of both minor and major injuries quickly, and (2) to supervise and care for the health of the men in the shop, with the object of keeping them fit and on the job. It also serves as a means of establishing a personal contact and confidence between the employer and employee, and it aids in discovering any dangerous occupations, machines, or appliances in the shop which may cause frequent injuries and which, therefore, must be more properly guarded. In this way proper safety appliances may be installed and it has been found that such appliances, together with a general regard for the welfare of the men have materially reduced accidents and injuries. While the value of health work is evidenced by a reduction in the number and seriousness of accidents, it is perhaps better shown in the increased efficiency of the men as indicated by increased production. Better relationships exist throughout the plant and there is a steady appreciation of health values.

THE MEDICAL UNIT OF A COMPANY

The medical service of the R. K. LeBlond Machine Tool Company affords an excellent example of what the medical department may come to mean in an organization.

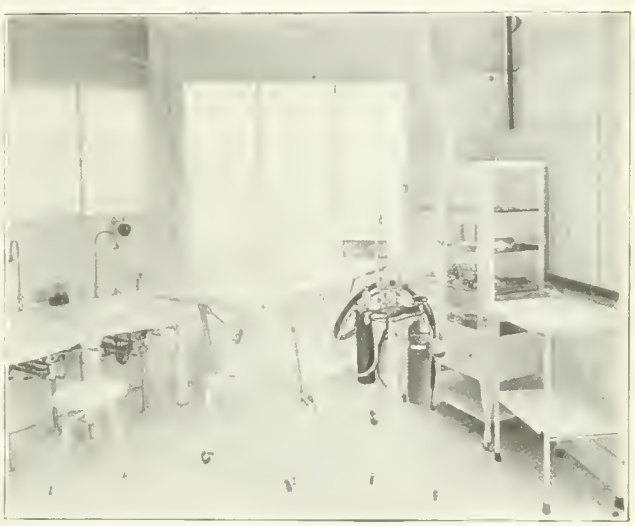
Designed primarily to care for the acutely sick or injured employee, its administration has broadened and become so effectual that prevention and welfare work overshadow corrective measures.

The mental welfare of the men is a matter of concern. Advice is provided on legal and financial matters and help extended in matters of personal adjustment or training in citizenship.

While we have an operating room for major operations, full equipped, in connection with our hospital we have had only one occasion to use it in the last two years, and that was for the partial amputation of a great toe.

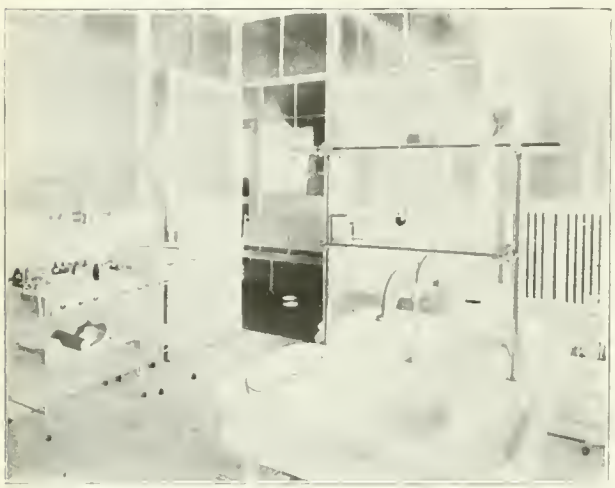
During the year 1919, there was 15,183 patients treated in our hospital, classified as follows: surgical conditions, 4,285; medical conditions, 5,136; re-dressings, 1,064; re-treat-

The hospital department of the R. K. LeBlond Machine Tool Company is equipped to take care of both major and minor work with the greatest possible expedition.



The operating room is fitted for the handling of major surgery, but so well has the preventive health work been done that its use has been requisitioned only once during the past two years.

ments, 3,192; and dental conditions, 1,506. This list includes every applicant for treatment, whether a new surgical case, a re-dressing, a new medical case, or a re-treatment.



Both medical and surgical care are provided for the men, the object of the service being not so much correction as keeping them fit.

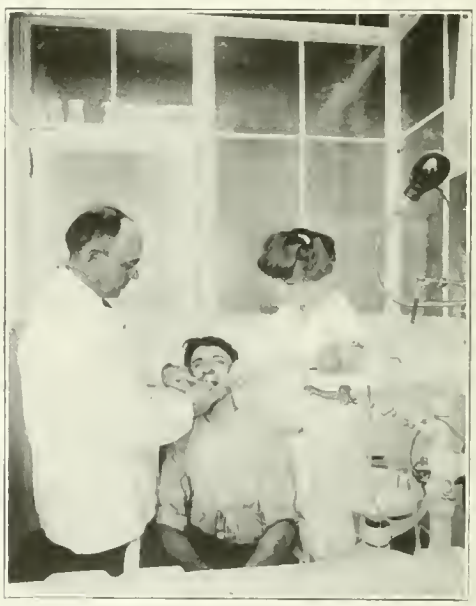
During the year no permanent disabilities were incurred; that is, no disabilities from which the injured did not entirely recover. There were no fingers lost, either partial or total, which is a remarkable record in view of the fact that machine shops are particularly productive of this type of injury.

Our eye cases show a marked decrease in number and severity for the year 1919. There were 979 foreign bodies extracted from the eyes, as compared with 1,302 in 1918, and 5,016 for 1917, with practically the same number of employees working. Of the eye cases only three were considered of sufficient importance or severity to be referred to an eye specialist. The foreign bodies were removed with the aid of a solution of 1 per cent cocain, and, when the piece had become deeply embedded in the cornea and there were indications of traumatic keratitis or impending corneal ulcer, a small disc of homatropin Hcl 1/40 gr. was used, a shield placed over the injured eye, and treatment given every two hours. With the exception of twelve cases the eye injuries were treated in our hospital, while the men remained on the job.

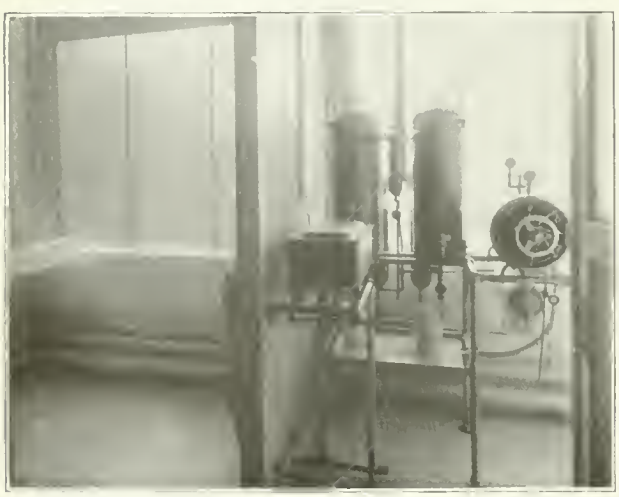
There were 190 days lost on account of accident incurred in the plant during the year 1919.

The Fatigue Factor in Accidents

During the summer months, beginning May 1 and ending September 30, an intensive campaign of accident prevention was inaugurated. These months were selected and given particular attention for the reason that fatigue is considered a prominent factor in the causation of accidents. This, however, did not prove true as the following data will show. Our records for this period show that there were sixty hours lost through injuries incurred in the plant and, since 1,000 men were employed, sixty hours meant a loss of 3.6 minutes per man for the period of five months. There was $6.90 compensation paid during the five months for these injuries.



Dental examination is made of employees periodically with a view to keeping their mouths in a hygienic condition. The work has afforded ample proof of the economic value of a dental dispensary.



The most approved type of installation is used throughout. The sterilization equipment is adequate for any emergency.

The sixty hours lost are distributed as follows:

During the month of May there were 16.2 hours lost; in June there was no time lost; in July there were 10.1 hours lost; in August there were 13.4 hours lost; and in September there were 20.3 hours lost.

The safety, sanitation, and health of the R. K.

LeBlond Machine Tool Company are under the supervision of the hospital department. It is the aim of this department to exercise as close and as careful a supervision over the human element

A self-service counter is provided for the men who do not desire a regular dinner at noonday. Everything is served that is usually handled at a counter of this kind.

as the engineer exercises over the inanimate machinery and technical parts of the plant.

Work of Dental Department

The dental department is under the supervision of a dentist who spends one hour a day at the plant. The dental department consists of a room, 8x10 in size, equipped with an industrial unit, cabinet, file, gas-oxygen outfit, and the usual small tools and appliances for performing extractions and prophylactic work. This department was equipped and furnished at a cost of approximately $1,800. The dentist is assisted by a nurse whose business it is to do the necessary clerical work, chart the patient's mouth, sterilize the instruments after each patient, and anticipate the wants of the dentist. With the help of a nurse the dentist is enabled to treat a great many more patients than he could without her assistance. His business is to examine the mouths of all of our employees periodically with the view of keeping the mouth in a hygienic condition. He also gives instructions as to the proper use of the tooth brush and dental literature by which the patient may discover the first symptoms of decay. We believe that if each employee cooperates with the dentist and at once consults his family dentist to have the needed work done, a maximum of efficiency will be maintained.

There were 1,506 mouths examined and charted during the year. Our records show that 96 per cent were in need of dental services; only 4 per cent were found to have clean mouths; 6 per cent were free from caries and responded to treatment readily; the remainder had disease producing symptoms known to dentistry, such as abscesses, pulp stones, inflamed pulp, ill fitting crowns, and ragged fillings, causing irritation.

The approximate cost per employe was about $1.12. Of the economic value of a dental dispensary there can be no question. The estimated saving to the company on extractions alone for the past year may be conservatively figured at approximately $2,200 in production.

Social Service Department

There are six particular fields of activity to which the Social Service Department devotes most of its time.

1. Absences from the plant, due to sickness or other causes.
2. Looking after the financial interests of the men by keeping them out of the hands of loan sharks and away from installment houses.
3. Personal attention to sickness or other difficulties in the home and to the amicable settling of family trouble.
4. Mutual Aid Society of the plant.
5. Legal aid and advice in the buying of homes or in the making of investments. With reference to this phase of the work the welfare director has the assistance of a competent attorney who spends one hour a day at the plant and whose business it is to give advice in legal matters, free of charge. His work, however, is primarily to keep the men out of trouble, rather than to get them out.
6. Aid in becoming citizens.

The Restaurant Facilities

Napoleon is credited with saying that an army travels on its stomach, and we are of the opinion that a man works on his stomach. With this idea

About seven hundred men are served with a regular dinner daily. The meal is well balanced, is served hot, and is served with such expedition that all men are busily eating within fifteen minutes from the noonday whistle.

in view we maintain a fully equipped restaurant and cafeteria. We consider this one of the main features of the Service Department.

About seven hundred men are served every day with a regular dinner, and about one hundred men who do not desire a regular dinner are served from a self-service counter. In order that the meals may be hot when served to the men, five large trucks are fitted with heated slabs. About eleven o'clock the waiters fill the plates and place them in these heated ovens. Three minutes before the noonday whistle blows the waiters begin to place the plates on the table, so that by the time the men arrive for dinner, about two or three minutes after twelve, the dinners are on the tables, ready for the men to eat. Everything is done in an orderly manner, and by 12:15 the men are all served and are busily engaged in eating their meal. Our hot meals, as a rule, consist of soup, one meat, potatoes, one vegetable, bread and butter, coffee, tea or milk, and a dessert. At the self-service counter are served soup, sandwiches, pie, cakes, fruit, coffee, and everything that is usually sold at a counter of this kind.

For the regular meal we have a coupon book of ten tickets which cost $2.50. This book is sold for cash or, if the men wish it, the amount is charged to their account and deducted from their salary at the end of the week.

Our dining room is a large beautiful room, on the third floor, running the length of the building, with windows on both sides, thus giving light, ventilation and sunshine,—a perfectly sanitary room for the men to eat in. The tables are of wood with vitrolite tops, each seating six men. Beautiful ferns and plants are arranged on opposite sides of the room which makes it a very pleasant room for the men at noon.

Every Tuesday and Thursday a musical program is given by our orchestra while the men are eating. The orchestra is made up of our own employees, who rehearse one hour a week.

Every Friday at 12:15 we have motion pictures, usually chosen for educational features, as well as for the giving of pleasure.

REPORT OCCUPATIONAL DISEASES

Every physician, states an Ohio law becoming effective May 4, who is attendant on or called in to visit a patient whom he believes to be suffering from lead poisoning, poisoning from phosphorus, arsenic, brass, wood alcohol, mercury, or their compounds, or from anthrax, or from compressed air illness, and such other occupational diseases and ailments as the State Department of Health shall require to be reported, must make such report to the State Health Commissioner within forty-eight hours from the time of the first visit. Reportable diseases are named in the Code, a penalty attached for nonconformance.

GROWTH OF THE NATIONAL SAFETY COUNCIL MEMBERSHIP

By LOUIS RESNICK, Director of Publicity, The National Safety Council, Chicago.

Like many other of the country's greatest institutions, the National Safety Council is the child of necessity. It is an organization that grew out of a great need felt by the managers of industrial plants who were doing pioneer accident prevention work during 1912 and the half dozen years immediately preceding it—a need for an exchange of experiences in this work.

Clearing House for Safety Information

No sooner had a few companies demonstrated what remarkable reductions could be made in accidents and what a great economic gain was yielded by accident prevention work than other companies all over the country became interested and began to burden the pioneers in safety with inquiries for information regarding their experience. So great was the demand for information of this sort that the idea of forming a national clearing house for accident prevention information suggested itself to a group of some two dozen men who were in charge of safety work in as many plants. The National Council for Industrial Safety, as it was then called, was officially organized at New York City, September 23 to 25, 1913, with the following executive committee: Messrs. R. C. Richards, Chicago & Northwestern Railway Company; C. L. Close, United States Steel Corporation; David Van Schaack, Aetna Life Insurance Company; Fred C. Schwedtman, Racine-Sattley Company; L. R. Palmer, chief factory inspector, State of Pennsylvania; H. M. Wilson, United States Government Mining Bureau; C. W. Price, assistant, Wisconsin Industrial Commission; Edwin R. Wright, Chicago; E. G. Trimble, Employers' Indemnity Exchange; G. L. Avery, Avery Company; Charles Piez, Link Belt Company; A. T. Morey, Commonwealth Steel Company; R. J. Young, Illinois Steel Company; R. W. Cambell, Illinois Steel Company; and W. H. Cameron, Chicago. The purpose of the organization was outlined by Mr. Campbell, the first president, as follows:

The National Council for Industrial Safety proposes "to promote the conservation of human life and its incidents in the industries of the nation, and to that end:

"(1) To establish a conveniently located headquarters for the maintenance of a clearing house of safety information, available to all concerned.

"(2) To encourage and promote throughout the country the organization of those engaged or interested in safety work into district and local councils, in affiliation with this National Council.

"(3) To hold annual congresses, at which all persons interested in accident prevention and kindred subjects may take part in practical discussion of vital problems and also have opportunity to examine carefully prepared exhibits; to publish and give wide distribution to proceedings of such congresses.

"(4) To encourage and assist in the practical standardization of safety devices, safe conditions, and practices.

"(5) To give the widest publicity, through its own publications and other channels, to all matters calculated to promote industrial safety.

"(6) In general, to initiate, promote, cooperate with and obtain the assistance of any and all activities or agencies calculated to conserve human life and its incidents in the Nation's industries; and to participate in and aid other activities for the welfare of the industrial workers of the country."

It should be noticed in passing that while the roster

of the National Safety Council has grown from a promise of fourteen memberships in 1912 to approximately four thousand industrial concerns, operating more than 7,500 plants and employing more than six million workers, in 1920, and, while the scope and service of the Council have gone far beyond the bounds of the original plans, the purposes of the Council as outlined by its first president are substantially the purposes of the Council today, and almost every member of the original executive committee is on the much larger executive committee of today and very active in the affairs of the Council.

Within a few weeks after the opening of the headquarters in Chicago the general manager, Mr. W. H. Cameron, through his contact with employers, realized the need of a definite weekly service to members. There resulted the development of the now extensive bulletin service of the Council. Eighteen thousand sets of three bulletins each, suitable for posting on bulletin boards, are sent to members of the Council each week. For a number of years the Council also sent out each week a special bulletin for executives. Recently this executive series bulletin has evolved into a weekly publication—the *National Safety News*—through which the executive officers and the men in charge of safety in the plants of members of the Council are informed of the very latest developments in the work of accident prevention.

Schools for Foremen and Supervisors

In the earliest years of the Council appeared the need of local activities in organized safety effort in industrial centers, a need for local organizations which would conduct meetings for workmen, foremen, and executives, and accomplish what it was impossible to effect through printed matter sent from the national headquarters. The National Safety Council therefore set about organizing locals, of which there are now forty in operation and at least a dozen in the process of formation.

The most successful feature of the local council work has been the development of schools for foremen and safety supervisors. It is commonly agreed by experts that a trained safety inspector is indispensable to the efficiency of accident prevention work in any plant. Many companies desire to select safety inspectors from among their own employees. The school conducted by various locals of the National Safety Council offer an opportunity for the training of such men.

In the latter part of 1916 the Council began to supplement its weekly bulletin service by monthly "Safe Practices" pamphlets, in each of which a particular hazard is discussed in detail and the safe practices in the construction and operation of the particular equipment involved described. This phase of the Council's service has been developed to the point where each Safe Practices pamphlet represents the result of extensive research work on the part of a high grade safety engineer with the cooperation of a conference committee of seventy-five of the Country's ablest safety engineers.

In 1917 the Council, realizing its need of men with technical experience, created an engineering department which since then has had in charge the preparation of all bulletins and Safe Practices pamphlets. This department now includes four safety engineers, who serve the membership of the Council not only in the preparation of bulletins and Safe Practices pamphlets but in investigating and answering all inquiries for technical information.

From the very inception of the Council the headquarters office began to develop a library. What began merely as a file of the information that was sent in by members has developed into the most complete library on accident prevention and industrial relations in the country. The National Safety Council library now has 10,000 booklets and pamphlets, 500 books, 5,000 clippings of special articles, and 1,500 blue prints and photographs—all devoted to safety or related subjects.

During recent years safety engineers and industrial managers who have given thought and attention to accident prevention have more and more come to see that Safety must be incorporated into the community life, not only in order to stop the alarming increase in deaths on the streets and in the homes, but to reach the workmen through their homes and to get them to respect Safety and to develop habits of caution. The National Safety Council is therefore carrying on a nation wide campaign for the organization of public safety.

GROWTH OF THE NATIONAL SAFETY COUNCIL MEMBERSHIP

Date	*Number of Members*
October, 1913	40
June 30, 1914	731
July 31, 1915	1,211
Aug. 1, 1916	2,120
Jan. 1, 1917	2,549
Jan. 1, 1918	3,484
Jan. 1, 1919	3,737
Mar. 1, 1920	3,854

The Council has not limited its educational work to its own membership. In some forty or fifty universities, through the efforts of the National Safety Council, the faculties have been induced to incorporate safety instruction in the curriculum. These universities are now giving consideration to the requirements of safety, both in instruction involving machine designing and plant management. The Council has for its objective during the coming year the securing of the adoption of instruction in accident prevention in all public and parochial schools.

NEW HARVARD COURSE

Intelligence in industrial management can hitherto be achieved by other means than in the long, hard school of experience, according to the *Boston Transcript*. The course recently instituted at Harvard is in charge of Dr. John M. Brewer, director of the Bureau of Vocational Guidance. The work will include job analyses and labor surveys and the solution of actual problems that arise in actual practice. Specialists from the several fields will present the following topics:

(1) The need for employment management.

(2) The qualifications of an employment manager.

(3) The installation of a plan for employment management.

(4) Selection of working force, including applications, job analyses, examinations and tests.

(5) Education, including Americanization, apprenticeship, education of foremen, education of operatives, vestibule school, upgrading courses, etc.

(6) Steadying employment, including the handling of absenteeism and tardiness, complaints, discharge, fatigue, work schedule, compensation systems, shop committees, transfers, labor turnover, etc.

(7) Service features, including financial aids, housing, insurance, legal aid, libraries, medical aid, profit sharing, plant publications, recreation, restaurants, safety, suggestion systems, etc.

(8) Due attention will be given to the arguments about and the machinery for cooperation in management, labor laws, labor problems, women in industry, and the relation of scientific management to employment management.

THE EXPERIENCE OF THE MEDICAL DEPARTMENT AT NITRO, W. VA.

By J. A. WATKINS, M.D., Medical Officer in Charge; Department of Industrial Medicine and Public Health, University of Cincinnati; Medical Director, Lunkenheimer Company, Cincinnati

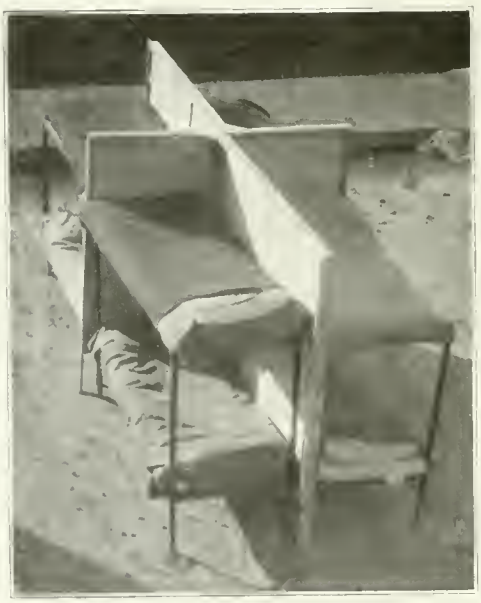
THE number or temporary rejections was relatively large. In this group fell mainly those afflicted with communicable disease which could be rendered non-infectious with an expenditure of time and labor consistent with operating conditions. Among this class was the venereally infected, the parasitic infested, and those suffering from acute exanthemata.

Enrolled with Disabilities Noted

Examination of the appended list showing the men enrolled with physical disabilities discovered, will at once illustrate with what leniency the medical examiners passed upon the qualifications of applicants for employment. It is also of interest, we believe, to note the large number of men who are physically imperfect. The relative number may be somewhat exaggerated because of the loss of the best men, physically, by reason of the enforcement of the Draft Law.

As stated elsewhere, if the men could perform even part of an honest day's work, and be of no danger to himself or his fellow men by reason of such association, he was allowed, so far as the medical examiner was concerned, an opportunity to so demonstrate his ability.

When men were passed for employment, the character of the work for which they were suited was specified on the examination card which was presented to the employment manager. It very often happened that after being employed for a length of time an employee for some reason desired a change of occupation. It was necessary in such case that he be re-certified by the examining medical officer in order that in his new position he would not be assigned work for which he was mentally or physically unsuited. He was not required to submit to a complete examination. His original physical examination record was consulted, however, and he was examined in some special manner for the purpose of certification. This procedure also was an excellent manner in which to watch for venereal infection and other infectious conditions, and a time and place of again coming in contact with the men in the plant. Such intimate and confidential relations between the employee and medical advisors proved advantageous.



A cubical bunking arrangement utilized at Nitro, W. Va., which has the advantage of simplicity and economy of arrangement, materials and space.

The applicant entered a dressing room where he was given a large canvas bag and a small canvas bag, with instructions to strip completely, putting all of his valuables in the small bag; all leather material, rubber, and felt to be kept to one side, and the remainder of his clothes put into the larger bag. He then proceeded to check his valuables, together with all leather, rubber, and felt materials, receiving in exchange for his bag a brass check with a number corresponding to the number on the bag. He then proceeded to a shower bath, at the door of which he was given soap. After taking a bath under observation of an attendant, he was, on emerging from the bath room, given a towel. After drying himself he proceeded to the record clerk, where he was given a numbered physical examination card. He was then placed on an automatic weighing scale where the height and weight were taken at one time and recorded on the card. He then proceeded to the examining room where he was given a complete physical examination, after which he was vaccinated against small-pox and inoculated for typhoid. A thumb print having been taken, he then turned in his brass check, received his belongings, was given verbal advice and popular public health and safety literature, passed into the dressing room, and proceeded to the employment office.

During the period of time elapsing between the time of turning in his clothes and calling for them at the window his effects had been searched

*This account is the second of three installments of an article on the experience of the medical department at Nitro, W. Va., which are being published in Modern Medicine. The third and last installment will appear in the June edition.

for vermin and drugs and passed through a high pressure steam sterilizer.

RESULTS OF PHYSICAL EXAMINATIONS

Total number rejected	621	or .8%
Temporarily rejected	6,697	or 8.8%
Immediately passed and employed	69,680	or 90.4%
Total passed and employed	76,377	or 99.2%
Total number of men examined	76,998	
Total number of examinations made	94,438	

One hundred ninety venereal infected refused treatment and deserted. The greatest single cause for rejection was for epilepsy, 102, 16.4 per cent, rejections having been made for this reason. Next in importance was active pulmonary tuberculosis, 85, 13.6 per cent, rejected applicants being in the infectious stage of this disease. Other causes of permanent rejection were:

Inadequate vision	51
Trachoma	45
Miscellaneous chronic and debilitating diseases	33
Uncompensated heart	20
Extreme old age and general debility	16
Discharging tuberculosis sinus	14
Deaf mutes	14
Mentally deficient	12
Extreme hernia	11
Asthma	10
Drug addicts	5
Tabes dorsalis	4
Cirrhosis of liver, aedema, and ascites	3
Loss of limbs	4

Temporary Rejections

Of the 76,998 applicants 6,697, or 8.7 per cent, were temporarily rejected for the following reasons:

Venereal infected (1.7% of men examined)	1,358
Measles	15
Mumps	5
Erysipelas	2
Diphtheria	2
Small-pox	8
Chicken-pox	4
Scabies	71
Suspected Trachoma	55
Delirium tremens	5
Parasitic infested (body lice, head lice and bed bugs, 3% of men examined)	2,362
For medical relief (3.6% of men examined)	2,778
Acute alcoholism	20
Total	6,697

It is of interest to note the large number of venereally infected and the parasitic infested weeded out, and also the large number which required immediate medical relief. Of the 1,358 venereally infected 1,120, 82.4 per cent, were acute gonorrhea; 210, 15.4 per cent, syphilis in an infectious stage; and 28, 2.2 per cent, were chancroid in the acute stage.

Some obvious physical disability was shown by 10,104 men, or 14.1 per cent, of those examined. In 3,667, 33 per cent, of these cases the abnormality was of sufficient importance to make it the subject of special record for future observation and treatment. In a total of 76,996 examinations, 2,928, 3.8 per cent, were found to be suffering from hernia of all types; of these, 2,728, 95 per cent, were inguinal; 41, 1.4 per cent, ventral or post-operative; 17, 5.8 per cent, femoral; and 3, 1 per cent, were epigastric.

In the follow-up work 17,550 re-examinations were performed. In 133 instances men were sent home who were found to be suffering from some cause of permanent rejection suspected, but not definitely determined at the time of original examination. The remainder were for the purpose of imposing remedial measures, occupational transfers, or prophylactic occupational disease work.

The physical examination of women was performed for exactly the same reasons as were the examinations of the men. They followed in a general manner the same character and the same requirements for employment were in general instituted. Examinations were performed by female physicians who worked under the direction of the Medical Officer in Charge of Physical Examinations. Rejections, both permanent and temporary, re-enrollments, and certification for specified employment were carried out as with the men.

The total number of applications for employment was 525 and the results of physical examination follow:

PERMANENT REJECTIONS

Epilepsy	1
Pregnancy of 2 months or more	3
Active pulmonary tuberculosis	4
Uncompensated heart	2
Vision (acuity inadequate)	6
Deaf mute	1
General physical disability	1
Total rejected (0.3%)	18

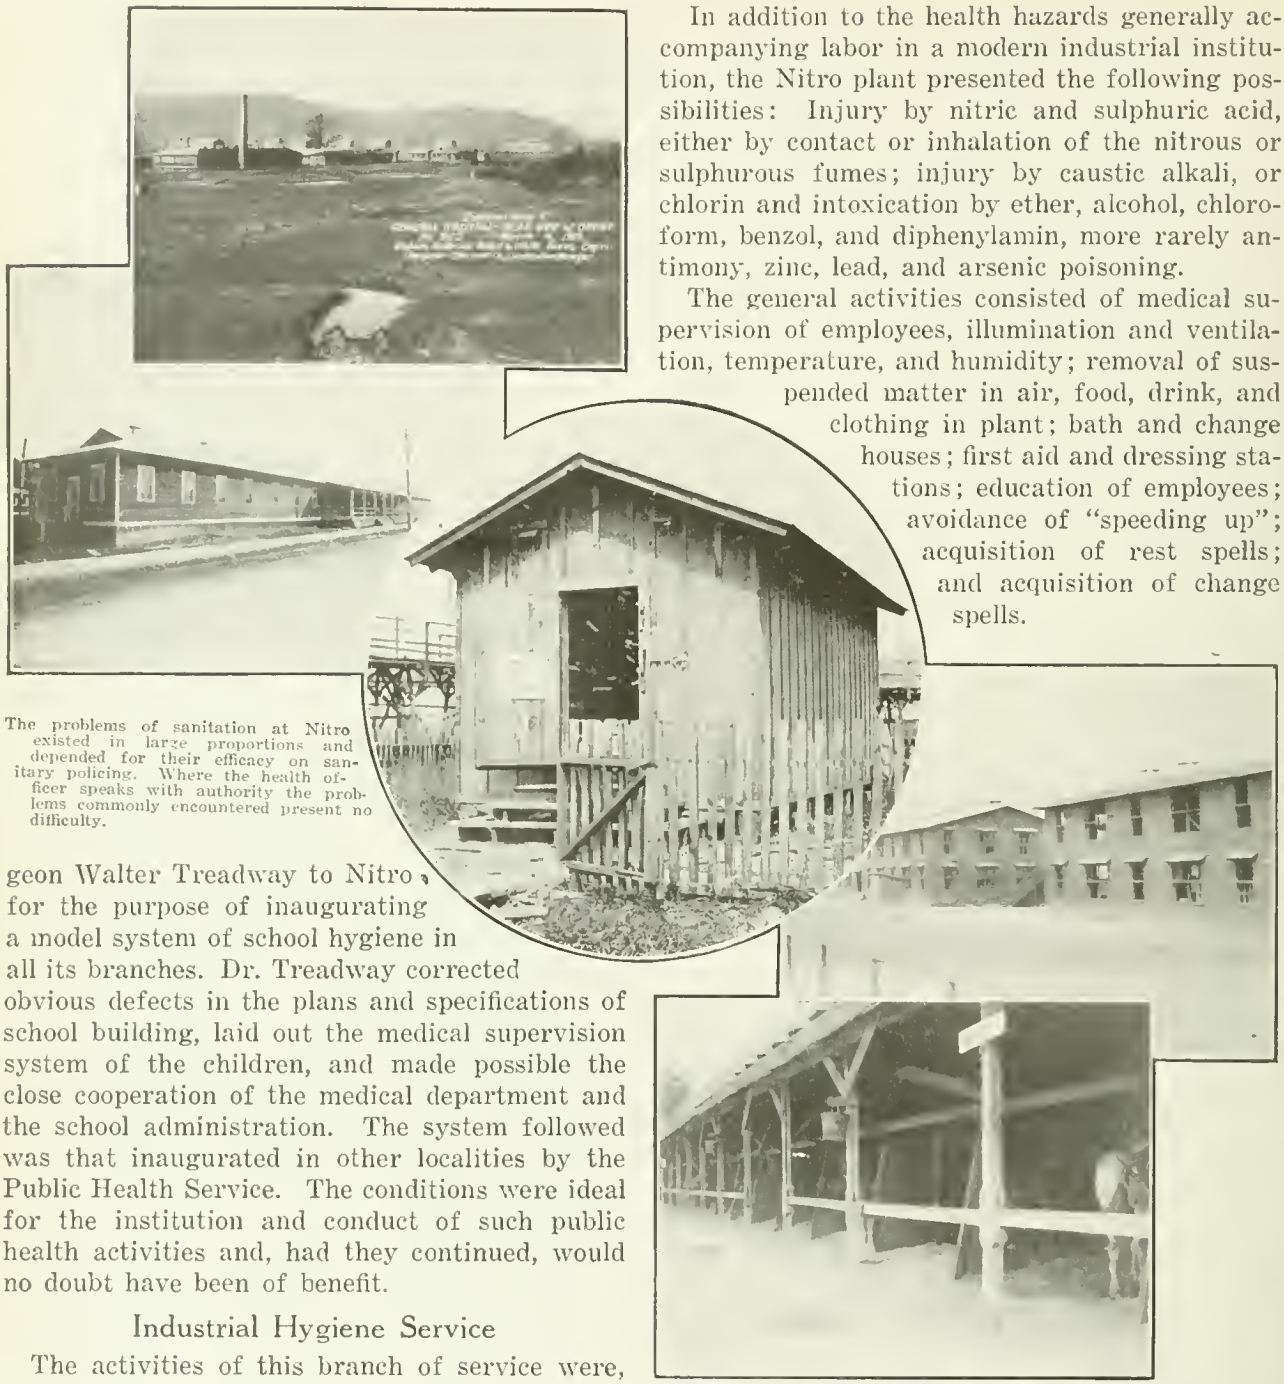
TEMPORARY REJECTIONS

Gonorrhea	1
Scabies	3
Pediculosis	1
Syphilis	1
Bronchitis (acute)	2
Total rejected (0.01%)	8 or .01%

WOMEN ENROLLED WITH DISABILITIES

Loss of one eye	4
Impaired vision	10
Impaired hearing	2
Compensated heart	5
Spinal curvature (all types)	14
Loss of one finger	3
Loss of four fingers	1
Acquired deformity of hand (limited motion)	1
Hernia—inguinal	1
Procidentia	2
Varicose veins (extreme)	29
Acquired deformity of ankle	1
Acquired deformity of foot	2
Total enrolled with disabilities (14%)	75
Passed and employed (96.6%)	507

The physical examination and medical supervision of the employees and their dependents extended to the school children. Upon request the Surgeon General detailed Passed Assistant Sur-



The problems of sanitation at Nitro existed in large proportions and depended for their efficacy on sanitary policing. Where the health officer speaks with authority the problems commonly encountered present no difficulty.

geon Walter Treadway to Nitro for the purpose of inaugurating a model system of school hygiene in all its branches. Dr. Treadway corrected obvious defects in the plans and specifications of school building, laid out the medical supervision system of the children, and made possible the close cooperation of the medical department and the school administration. The system followed was that inaugurated in other localities by the Public Health Service. The conditions were ideal for the institution and conduct of such public health activities and, had they continued, would no doubt have been of benefit.

Industrial Hygiene Service

The activities of this branch of service were, for administrative purposes, divided into two classes: (1) General activities which had to do with the acquisition and maintenance of conditions which are applicable to industries in general; and (2) special hygienic measures which dealt with conditions brought about because of the special industrial processes carried on at Nitro. In the latter, we profited by the experience of others engaged in similar work. Particularly are we indebted to Dr. W. G. Hudson, of the Du Pont de Nemours Co. Only a brief discussion can, of course, be given here of these activities, the industrial processes carried on, or the attendant dangers.

In addition to the health hazards generally accompanying labor in a modern industrial institution, the Nitro plant presented the following possibilities: Injury by nitric and sulphuric acid, either by contact or inhalation of the nitrous or sulphurous fumes; injury by caustic alkali, or chlorin and intoxication by ether, alcohol, chloroform, benzol, and diphenylamin, more rarely antimony, zinc, lead, and arsenic poisoning.

The general activities consisted of medical supervision of employees, illumination and ventilation, temperature, and humidity; removal of suspended matter in air, food, drink, and clothing in plant; bath and change houses; first aid and dressing stations; education of employees; avoidance of "speeding up"; acquisition of rest spells; and acquisition of change spells.

The special activities consisted in the avoidance of industrial intoxication or injury, either rapid or insidious, by the various harmful chemicals manufactured or used in the manufacturing processes at Nitro. This was supplemented by facilities for the early diagnosis and treatment of intoxication or injury, did such occur. Working conditions were made as free of danger as possible, *i. e.*, the building, the industrial process, and the immediate environment were made as safe as consistent with the proper performance of the work. Then the workman was protected by clothing, appliances, equipment, and facilities

aiding in or preventing intoxication or injury; and, finally, by means of popular education, employees were instructed in the dangers of their occupation and so were able to avoid untoward effects.

Workmen and their dependents were housed in Nitro in either one of two ways, in barracks or bungalows. Both of these types of housing structures were of the characteristic design and material used at Nitro, *i. e.*, frame and plaster board with paper and composition roofing, and gas, heat, electric light, public water, and sewage facilities. Such quarters were plainly and sparingly furnished, but adequately furnished with sleeping and sitting room furniture.

The private rooms for the female nurses were adequately furnished with bedroom furniture.

Of the barracks there were sixty-seven, of three different designs; of the bungalows, 1,253, of three different sizes and designs. The different races, more especially colors, were segregated in definite areas. In general, certain districts were assigned to skilled and unskilled workmen. Most unmarried men were housed in the barracks, while married men, especially if accompanied by the families, were quartered in bungalows, with whom, in many instances, single men occupied in the more responsible or executive positions were quartered. A nominal charge was made for rental and the facilities afforded. It is believed that these bungalows met the requirements in a satisfactory manner, on the whole, though a few structural changes were later made and a change made in the heating and ventilating installation in the barracks. What undesirable, unhygienic conditions that did exist came about by overcrowding, unhygienic habits of occupants, or failure of those entrusted with the proper cleansing and care of the quarters rather than from any basic fault of the housing structure.

Though the responsibility for conditions of housing held throughout the area, little attention was given bungalows housing the families of the skilled workmen or those occupied by the more responsible of the workmen. Constant attention, however, was given to those quarters occupied by laborers, particularly the barracks. The steps taken to acquire and maintain proper hygienic conditions in these quarters may be of interest.

In each barracks an inspector, working under the direction of a medical officer, was responsible for the maintenance of given conditions of temperature, illumination, ventilation, the compliance of men with barracks' rules, such as the anti-spitting rule and the proper cleansing of barracks by porters. The inspector also reported to the medical officer any matter bearing on the proper care of these quarters. The efficiency of this plan depended entirely upon the ability, intelligence, and character of the inspector in charge, especially the discipline he maintained over the occupants.

When parasite-infested beds were discovered, they were first entirely cleansed and sterilized in either the steam pressure chamber or in the cyanide house and then laundered. The cyanide house[1] was an air-tight room built of tongue and groove floor boards and tar paper, the heavy bevel edged door on either side being similar to the doors on a large ice box. Racks on which bedding was placed were in tiers on either side, while the tubs in which the gas was generated were placed two on each side. Electric fans and light were supplied. The cyanide was dumped into the acid in the tubs by an arrangement operated from the outside of the building. The plan proved to be both effective and economical, as both acid and cyanide were procurable at the plant. During the period covered by this report 2,526 cases of pediculosis were discovered; 22,128 pieces of clothing and 24,713 pieces of bedding were sterilized for the elimination of vermin.

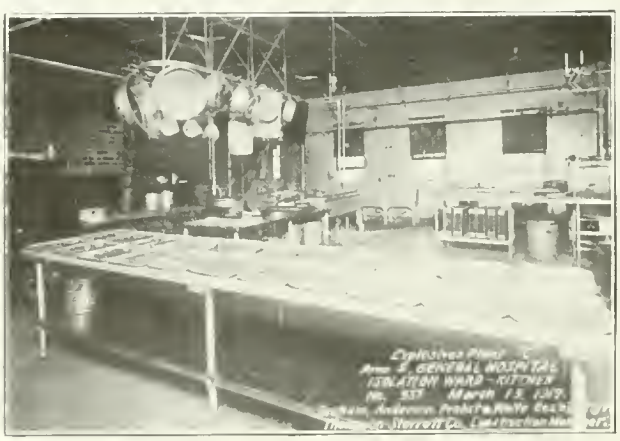
1. For further information, see Public Health Reports.

Beds were of several types. Canvas cots and single woven mattress cots were used, though double-deck iron bunks predominated. Men were first assigned to these barracks and given not less than 110 square feet per man. Housing became such an urgent matter, however, that overcrowding became unavoidable. To meet this, the following cubicle system was designed and placed in operation. It proved satisfactory and is recommended. By placing four men close together, but separated by the shields, an open space of greater, area, and hence greater safety, was procured. A safe grouping with about 100 per cent increase in capacity was thus made possible.

A view of the mess hall of the General Hospital, showing the dining rooms for doctors and nurses.

Active measures for venereal control were instituted at the outset. Although the work was carried on as a distinct branch of the medical department, its activities extended to that of other departments, the work of these departments being discussed elsewhere in this article.



The kitchen of the isolation ward, General Hospital, Nitro, W. Va.

Among means for the discovery of the infected were the medical examination of all men arriving at Nitro; all applicants for change of occupation; bi-monthly examination of all mess hall employees; unannounced examination of men in barracks at night and at out-patient relief and dressing stations, when men reported for injury or other sickness. Many men were in this way examined at intervals; 76,998 were examined for venereal infection a total of 103,206 times. Such opportunities for the discovery of venereal infection were aided by educational propaganda which encouraged men to report voluntarily.

No man was refused employment because of infection. He was, however, immediately taken charge of by the medical department, being either hospitalized or partially isolated, and placed at work. He remained in the hospital only until it was safe for himself and his fellow workers. In some instances men were isolated. In carrying out this plan, the patients first received instruction as to the nature of their malady, how it is contracted and spread, the dangers thereof and how to avoid them. They were not allowed to perform certain classes of work and were housed in definite barracks. When cured or rendered

non-infectious, they were discharged from observation.

Treatment of venereal cases was performed only at the isolation hospital or the genito-urinary dispensary located in the venereal barracks. Much of the routine work was carried out by graduate female nurses and trained male nurses, under the supervision of the Medical Officer.

A propaganda campaign was directed against ignorance regarding venereal infection, and under the circumstances was somewhat effectual, as only 13.5 per cent of the venereal cases contracted the infection after arrival at Nitro. This educational campaign was divided into written and spoken work. The written propaganda consisted of circular letters, posters, pamphlets, illustrations, and photographs. The more influential part of the work consisted of private talks to each workman at the time of employment, to groups of isolated working gangs, the instruction of foremen, barracks talks, and lectures at the Young Men's Christian Association.

The following table shows, in condensed form, the medical relief afforded the venereal infected at Nitro.

MEDICAL RELIEF VENEREAL DIVISION

Disease	Admitted
Balanitis	2
Chancroid	141
Epididymitis	59
Gonorrhea	1,663
Gonorrheal Ophthalmia	1
Herpes Genitalis	1
Inguinal Adenitis	24
Prostatitis	21
Syphilis	328
Urethral Abscess	3
Total	2,243

of interest: Sixty-two per cent of the venereally infected acquired the disease while under the influence of alcohol. Of the total number affected with gonorrhea, 4.6 per cent developed complications. Acute gonorrhea required an average of four days in bed. Complicated cases of gonorrhea required on an average of eight days in bed. Chancroid patients remained in the hospital an average of twelve days. The time limit in complications with gonorrhea were as follows: First week, 9 per cent; second week, 28 per cent; third week, 37 per cent; fourth week, 14 per cent; fifth week, 12 per cent. Ninety-eight per cent of syphilitics coming under observation of the medical department were rendered non-infectious before they deserted treatment. Fifty-five per cent of the syphilitics gave a positive Wassermann reaction within two weeks after the initial lesion appeared. Of all the intravenous injections of salvarsan, untoward results were experienced in only four patients, in whom "sore arm" developed.

An exceptional opportunity was offered at Nitro to demonstrate the feasibility of the prevention of the spread of communicable disease. We have demonstrated our ability to control the mosquito,

Store house of the General Hospital at Nitro, W. Va.

the rat, and the louse; and we have also demonstrated our inability to control the remaining link in the chain, *i. e.*, man. At Nitro it was possible to control the man to a far greater degree than the average urban health officer is able to exercise such restrictions. The results of the experience at Nitro demonstrate the results that can be obtained where modern measures can be imposed and carried out. An exception, of course, is made in the case of influenza, which evaded all preventive efforts. Though advance knowledge of the pandemic was had, and fully outlined, our methods of procedure had been decided upon and all the contemplated precautions taken, we were nevertheless overwhelmed by the undue prevalence of this disease.

taken to the physical examination building, where they were bathed, vaccinated, subjected to a medical examination, and their clothing disinfected in the routine manner described elsewhere. The parasite-infested were sent to the detention barracks; the infectious, including the venereal, to the isolation hospital; the sick to either the general hospital or out-patient office, depending upon the severity of the case. Doubtful cases were held for observation, and certain cases, such as drug addicts or the mentally afflicted, received special measures. The apparently clean and well were sent to certain barracks, where they remained from five to seven days before being assigned to permanent quarters. Ordinarily it would seem that the introduction of the infectious, or infested,

Venereal disease	1,358
Trachoma	45

Workmen usually arrived at Nitro during the day on special trains. They were immediately

would be prevented by such precautions if carefully and consistently carried out. Though no communicable disease was reported as so escaping the vigilance of the medical officers, yet this department repeatedly passed parasitic infested men or clothing. These were found in the barracks, where a daily inspection of all beds, clothing, and effects was made under the direction of a medical officer.

Popular public health literature, and venereal disease and accident prevention pamphlets were distributed, and the men told how, when and where to receive prophylactic or remedial relief. It is believed that such measures assisted in the prevention of the spread of communicable disease. In the bungalow section dependents of employees were inspected and vaccinated, but not

A doctor's private office in the General Hospital.

examined physically, before being assigned to quarters. Many infectious cases were thus discovered and properly isolated, though a few in the incubation period were passed.

There were thirteen mess halls, the employees of which were examined by a medical officer every two weeks. During this period of time, 6,198 medical examinations of food handlers were performed, thirty-three of whom were disqualified. Four suffered from tuberculosis which had escaped the original medical examination; sixteen had contracted venereal infection; two were found to be typhoid carriers; three had scabies, while the remainder were disqualified because of personal uncleanliness.

In addition to these precautionary measures, an isolation hospital was equipped and conducted as described under the section dealing with medical relief. In some cases, as for instance the presence of communicable disease in the person of an infant or small child, the case was not separated from its mother. Again, if it was impracticable to take the mother away from the household and her domestic duties, house isolation was resorted to. In these cases strict quarantine of the house and isolation of the case were carried out with good results. The system of control was assisted to a great extent by the inauguration and conduct of a visiting nurse organization. The duties of the visiting nurses did not vary a great deal from those required of such personnel in many urban communities; but, because of the unusual status of the medical department at Nitro, a very close supervision was possible and was attended with exceptional results. In addition to the above activities, an extensive system of public education was carried out both by means of lectures, talks, and a system of written propaganda leaflets, and circular letters. It was found that the acquisition of cooperation in order to carry out isolation measures depended to a great extent upon the knowledge and understanding of the laymen as to the modern conception of the cause, the prevention, and the cure or treatment of disease.

As a part of the system for the prevention of the spread of communicable disease, universal vaccination against small-pox was attempted. Of 76,998 workers examined, only twenty-one refused to be vaccinated against small-pox, and there was approximately 15 per cent of "takes" in small-pox vaccination. The fact may in part be explained by reason of the advanced age of many of the employees, most of whom had not been successfully vaccinated for from ten to forty years, and not only many children but many adults here were first vaccinated. In vaccinating against small-pox, careful methods of procedure as were possible under the circumstances were carried out, but no dressing or shield was applied. It is gratifying that of the 80,174 men, women, and children vaccinated, only nineteen infections were seen, and these were found in cases where violations of physician's instructions had taken place. A large number of very severe reactions, however, were seen. Eight cases of small-pox were imported, but no secondary case developed.

MODERATION IN ALL THINGS

The characteristics of people more than seventy years of age, says Dr. George L. Meylan, director of the gymnasium of Columbia University, are that they do not worry, have happy dispositions, and eat, drink, exercise, and enjoy themselves moderately.

"There is abundant evidence," says Dr. Meylan, "to justify the belief that the average duration of life could be increased from ten to twenty years by the adoption of the principle 'moderation in all things,' deaths by infectious diseases and violence excepted."

SCIENCE AND INDUSTRY

The country under occupation by the Allies in the vicinity of Cologne includes some of the best examples of German chemical industry, and it is interesting to learn that the great factories on the banks of the Rhine have been visited recently by a deputation of British experts. Their report has been issued and, generally speaking, confirms our previous knowledge of the Germans' activity and their remarkable steadfastness of purpose. It is not so much initiative or ability that they possess as a determination to work out detail and to adapt the lessons of the laboratory to commercial ends. They have turned chemistry to national account, and that is the main lesson of the report to us. In Germany scientific investigation is encouraged, the best advice is gained, and men who are trained to a high level of efficiency are well remunerated. This policy, begun years ago, succeeded, and explains why Germany took a lead over other nations in producing fine and heavy chemicals, pharmaceutical products, and dyestuffs. The report should have a healthy and stimulating effect on the chemical industries of this country. We are not behind in ability, but we are slow to reap, commercially and nationally, the harvest of our scientific attainments.—*The Lancet.*

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

BROADENING THE ATTACK UPON TUBERCULOSIS

High hopes were entertained ten years ago in regard to the efficiency of the sanatorium as the principal weapon in our fight against tuberculosis. It was believed, and rightly believed, that the establishment of municipal and county sanatoriums of sufficient capacity was the first step in a comprehensive attempt to limit the ravages of this disease. We were inclined, however, to overestimate the gains that could be secured by this first step alone. Sanatoriums have been opened,—in large numbers, and in certain states there is today even a surplus of unfilled beds. We are beginning at last to obtain reports of the ultimate effectiveness of the sanatorium; and these reports are in some respects discouraging. Few can doubt that sanatoriums accomplish most gratifying results in the improvement of many an individual case. Yet when we recall the fact that of 1,056 patients discharged from Massachusetts sanatoriums between 1912 and 1914, only 29 per cent were in good condition and at work in 1916, —and that of 2,701 patients discharged from Wallum Lake, R. I., between 1906 and 1915, only 31 per cent were in good condition and at work in 1917, it seems clear that the maximum possible results are scarcely being realized from the sanatorium as an instrument of healing.

There appear to be at least two clear reasons for the incomplete achievements of the sanatorium in the past; and both of them are beginning to receive the attention they deserve at the present time.

The first defect in our utilization of the sanatorium, as has long been clear, is the fact that we have begun treatment too late, when the disease had proceeded too far for curative measures to prove of avail. In but few states or cities do the cases of tuberculosis reported in a given year exceed the reported deaths, while as a matter of fact we know that there exist in any community about ten cases for every death. The mortality rate is, of course, generally between 100 and 150 per 100,000; but studies carried out by Dr. Armstrong at Framingham, Mass., and by the District Nursing Association of Providence indicate that a random sampling of the population will show between 1 and 2 per cent affected with tuberculosis. Intensive search for tuberculosis cases at Framingham, reported by Dr. Donald B. Armstrong at the recent meeting of the National Tuberculosis Association in St. Louis, increased the number of known cases of tuberculosis from twenty-seven to two hundred in the examination of 13,000 men. On the other hand, effective measures for the treatment and control of these newly discovered cases has reduced the mortality from tuberculosis from 121 per hundred thousand to eighty-four per hundred thousand in three years. At the beginning of the Demonstration the ratio of active cases to deaths was three to one. This ratio was increased during the first year of active work to nine to one. There is relatively little object, according to Dr. Armstrong, in educating the public regarding the danger of infection from the known tuberculous cases if two-thirds of the actual cases in the community are unknown, and therefore not receiving treatment.

In connection with predisposition to disease, the inimical conditions associated with certain industrial pursuits need to be the object of specially adapted sanitary measures. Published data regarding the mortality experience in certain industrial groups reveal an undue percentage of deaths from tuberculosis. Whatever the underlying causes, all contributing factors need to be accurately measured, and whatever motive actuates the health activity, whether it is the outgrowth of an efficiency or a welfare movement, half-way measures in tuberculosis control are foredoomed to failure. Success can be counted on only in a broadly inclusive health administration.

The first essential in the present-day anti-

tuberculosis campaign is the detection of these cases in their early and curable stages. This means on the one hand a renewed effort to educate the public as to the importance not only of prompt recourse to medical assistance on the first signs of illness, but of systematic medical examination at regular intervals in the absence of any such signs. It means, on the other hand, the education of the medical profession in the difficult and neglected art of diagnosing tuberculosis through the establishment of special clinics, permanent or itinerant, and the provision of a special consulting service such as has proved so brilliantly successful at Framingham and elsewhere. The development of a strong public health nursing organization for the preliminary detective work which brings so many cases to our clinics is of course an essential part of the machinery for the discovery of the early case.

There is another defect in the present sanatorium system which is almost as important as the one just under discussion. The patients not only enter these institutions too late; they leave them too early. The average period of residence in most sanatoriums is under six months. In six months some patients are really cured and stay cured. Some die or continue to suffer a progressive increase of the disease. The greater number, however, improve and continue to improve so long as they remain under favorable sanitary and hygienic conditions; but when they go home to the factory and tenement, the infection quickly lights up again. It must be recognized that for a certain definite proportion of tuberculous cases what is needed is not a *cure* in the sense of a transitory treatment, but a permanent change in the conditions of daily life.

A permanent sanatorium residence is, of course, neither necessary nor desirable for such cases, even if it were economically within the bounds of possibility. What is necessary is the creation of living and working places, if possible of communities, in which are provided environmental and social conditions that permit the arrested case to retain his health.

Until we get early cases for treatment and return the arrested cases after treatment to an environment in which the ground gained may be held, we must say of the sanatorium what the wise prelate said when told that Christianity had failed: "It has not failed. It has never been tried."

1. Am. Rev. Tuberc., III, 276.

THE NEW SURGEON GENERAL

THE appointment of Dr. Hugh S. Cumming as Surgeon General of the United States Public Health Service should mark the opening of a new and important chapter in the history of the public health movement in America. Dr. Cumming has had a long and distinguished connection with the Service which he is now to lead. He has represented its interests in many parts of the world and has a wide knowledge of the problems of international quarantine which are of such peculiar importance; and he has also taken a notable part in the investigations of sanitary problems at home through which the Service has done so much to further the advance of that fundamental scientific knowledge upon which practical sanitation must be based. General Cumming takes office with the most cordial good wishes of the health workers of the country.

There has been gradually built up in Washington a National Department of Health of which the Nation need in no way be ashamed. Yet the rapid growth of the public health movement in general makes it essential that the Service should be expanded far beyond its present modest proportions. We are apt to hear a great deal about governmental economy in the year before a national election. Some economies are wise, however, and some are foolish. The niggardliness with which Congress last year crippled the Public Health Service was of the latter sort. General Cumming will find widespread public support for a broad and statesmanlike plan of expansion which shall bring the Public Health Service to the highest possible usefulness as the guiding influence in the nation wide and continuous war against preventable disease and death.

EDITOR.

PUBLIC HEALTH SURVEYS

By HAROLD B. WOOD, M.D., Dr. P.H., Acting Assistant Surgeon, Office of Industrial Hygiene, United States Public Health Service, New York City

A PUBLIC health survey is an accounting of the health conditions and needs of a community. It is not simply a compilation of statistical matter, but a descriptive report of all local influences of community social welfare. It is not a method for criticism, of public exposure of human actions, but constitutes a systematic method for determining practical public needs and for developing cooperative individual enthusiasm with public effort.

WHAT IS A SURVEY WORTH?

Public health surveys show conditions in their true perspective and enable the consideration of all factors in formulating measures for disease control. Unsuspected conditions are brought to light and thereby become correctible.

Surveys yield necessary timely suggestions and are educational in that they relate to conditions which are actually of local importance.

The value of compiled statistics and questionnaire reports is arrived at only by checking them against surveys of existing conditions, they serve as the only rational basis of budget making.

The purpose of a health survey is to detect the presence and correlation of all conditions and factors affecting health and for formulating practical and economical measures to decrease disease and increase comfort. No survey is a success until it has accomplished all these objects. A survey must be strictly non-partisan but, while occupying a neutral position, it legitimately considers the local methods of filling the positions to be occupied by the public servants to whom is intrusted the general program of bettering health conditions.

A survey may be a general health survey of a municipality or of a rural district to determine the existing conditions of all factors which pertain to health, or it may be a compilation of data in reference to some particular social phase or disease. It may also be a survey, for either of these purposes, of some particular industrial plant or of a group of industries.

General municipal surveys may be very wide in scope, as is illustrated by those made in Springfield, Ill., Topeka, Kan., New Haven, Conn., and in Charleston, W. Va. They may be more restricted in their field, as was the case in the survey of Birmingham.

A detailed report of a survey is of much more than local interest. Communities of equal size and latitude have much the same problems to face, and a careful survey of one will be of assistance to the others in the solution of their problems. It is easier to understand the true significance of conditions when a comparison is made with those of other localities. A report of a survey therefore becomes a municipal textbook. Within the municipality chiefly concerned, a survey serves as a guide for city planning, municipal development, health activities, and charitable services, as well as a useful report for state activities.

The expense of a survey depends upon its extent and should be met by the community concerned. A brief study of the vital statistics and disease records, with an inspection tour among the factories, will clearly indicate the probable need of a survey and whether the cure will be worth the treatment. Whether the recommendations should all be adopted depends upon the local value given to comfort and health. Lives are balanced against dollars.

Partial Surveys and General Ratios

A partial survey of a district is even of considerable value, as it will reveal some unexpected conditions; but it is fallacious to make a partial survey, as of certain selected blocks or through a banded section across a city, and expect that the results found will obtain for the entire city, or that an approximate estimate for the city may be deduced from the conditions found in any given section. A careful survey of a given section of a city will reveal the conditions existing therein, and not what may be found in other portions populated by other races, built during some other period of time, or which may be constructed or maintained according to other standards of hygiene and social or industrial development. A survey of one typical block of the east side of New York will give a very close idea of the conditions of adjoining blocks populated by the same class and race, but not of any other section of the city.

This limitation of partial surveys is shown even in the work in small towns. In a mosquito survey in Pennsboro, W. Va., it was found that a certain section was heavily infested with breeding

mosquitoes but other districts were comparatively free, although they offered just as ample opportunities for breeding. The explanation was not difficult, but the point was illustrated that the mean general ratio of breeding could not be estimated from a partial survey. Even in a statistical survey of influenza, the result of judging a city by a partial survey is well illustrated by the results obtained in Schuylerville, N. Y. The main street of the town is fairly typical of the social and racial conditions, as it contains some of the best residences and some of the worst living quarters of this neat village. In the entire town, 15.6 per cent of the population had influenza during the outbreak, on this one street 22.6 per cent; of the families involved, the town showed 40 per cent infected, this street 43 per cent; but among the involved families 61 per cent in the town and only 47 per cent on this street contracted influenza. A survey, to be even approximately correct, as is herewith shown, should cover and include the entire district it is expected to represent. Percentages of conditions for large districts cannot be accurately estimated by partial compilations.

One of the chief purposes of a survey is to help the people who are locally concerned. The investigator loses no opportunity to offer helpful suggestions wherever needed. As the survey progresses the attention of the person who owns or maintains the unhealthful condition is attracted until he is convinced of the necessity of a change. Then the best practical needed improvement is explained to him, but no person should be asked or expected to make any change which obviously is beyond his powers to install or to maintain. People should not be asked or be obliged to institute any improvement which they actually cannot or will not properly conduct. Where people have not the financial or intellectual ability to equip and maintain the most desirable sanitary or hygienic improvements, some other solution of their problems should be reached. They should be made to realize the importance of the advanced steps and to go as far as possible, for it is the direction and not the length of the step which counts.

Scope of City Health Surveys

The general scope of a municipal survey outlined herein must necessarily be brief. The details should be worked out before the survey is undertaken, in order to promote efficiency and to prevent needless waste of time and overlapping of activities. As each factor is uncovered and studied, its cause and effect should be determined as nearly as possible, consistent with its relative general worth, and the correlation with other conditions be determined. Throughout the survey helpful hints are given to the people who need them and when the need is found to be urgent.

The municipal health survey could be conducted along the following general plan:

Introduction
- Brief historic outline
- Geographical location
- Geological formations
- Racial settlements and distribution
- General review of public health and physical efficiency
- Industrial developments

Vital Statistics
- Population, growth, and influencing factors
- Birth and death rates, giving trend and reasons
- Influencing factors and how to control them
- Racial characteristics of birth and death rates
- Reportable diseases, prevalence, and rates
- Methods of control and their effects

Child Welfare
- Prenatal influences, effects, solution
- Infant mortality, factors, causes, and solution
- Pre-school problems

School Children
- Statistics, distribution, effect of location upon schools
- Prevalence of diseases among school children, control
- Medical inspection
- School buildings and grounds

Communicable Diseases
- Statistics of outbreaks; sources and methods of control
- Public protection against disease
- Educational work done and needed

Tuberculosis
- Prevalence, factors, distribution, causes
- Local modes of transmission, house influences
- Dispensary effects, and community needs

Typhoid Fever
- Prevalence, transmission, protection

Venereal Disease
- Dangers, prevalence, prevention

Food Supplies
- Conditions of production and storage
- Adulteration and wholesomeness
- Degree of inspection and results
- Disposal of spoiled or poor foods
- Prevalence of diseases among handlers

Milk Supply
- Amounts, source, distribution, availability
- Safety and cleanliness, city standard
- Bacterial counts, causes, variations, trend

Water Supply
- Source, safety, quality, distribution
- Protection, control, results

Sewage Disposal
- Methods, proportion, distribution
- Safety, local effects, treatments of sewage

Garbage Disposal
- Methods, desirability, nuisances, control

Street Cleaning
- Methods of collection and disposal of rubbish

Personal Hygiene
- Standards of living and effects
- Overcrowding, housing conditions, tenementation
- Condition and use of yards and lots
- Parks and playgrounds

Industrial Hygiene
- Kinds, distribution, and sanitation of factories
- Occupational diseases, prevalence, and control

Industrial accidents, prevalence, and control
Sanitary improvements, and social welfare
Health Department
Development, methods of appointment
Divisions, efficiency and needs
Activities, methods, results obtained
Budget; distribution and needed changes
Recommendations

Rural Surveys Are Educational

Rural health surveys are essentially educational in aspect because it is the personal suggestions given at the time which are the principal factors of public benefit. At the same time, however, statistical data are obtained to show the actual conditions found. This information is needed for planning future campaigns and for preservation to be used at a later date for comparison with future records to show the results obtained.

For rural survey work automobile transportation is advisable. The investigator should be a medical man in order to diagnose diseases found, because in the country there is a much greater proportion of unreported or unrecognized diseases than in the cities. A public health nurse should accompany the investigator to give instruction in child welfare, prenatal care, cookery, and household economics where needed for the safeguarding of health. Besides the oral suggestions, the farmer's family should be supplied with public health literature. Only that which is apparently needed and will obviously be read should be distributed. A one page list of simple health directions, couched in local terms and relating to conditions which actually are of local importance, should be left at every house. Besides this, an assortment of more complete pamphlets should be carried to be left as indications warrant. These pamphlets should separately cover such subjects as the care of the baby, safeguarding the health of children, the care of sick persons, the contagious diseases, clean milk, pure water, care of foods in the home and for marketing, destruction of insect and animal pests, and similar subjects of local importance. Discretion should be used in choosing which literature should be left, just as in giving sanitary suggestions, even though obviously needed.

The information collected and the appropriate suggestions offered during the rural survey would probably include the following subjects: name, address, and size of family; recent births, deaths, and reportable diseases; foods marketed and address of market; schools attended; source, safety, and protection of water supply; means and safety of sewage disposal; protection of purity of streams; condition of barn with scoring of dairy; care of the milk and other marketed products; health conditions of employees; family habits of living; measures taken to guard against communicable disease; history of typhoid fever and dysentery, with detection of suspicious carriers.

Questionnaire surveys are the least expensive but the most unsatisfactory. A large number of conditions, industries, and communities may be investigated by this method, although the collected facts are always open to dispute, as the answers are submitted by persons who are personally interested and therefore purposely or unconsciously biased. A list of questions sent by mail to a large number of persons will usually be answered by only those most interested. The returns may equal only one-fourth or one-tenth of the inquiries. The persons answering, being most interested, usually have the best conditions, for through their previous interest attention has been given to the points in question. The persons who do not reply have usually the worst conditions and are the ones most in need of the help which would result from the survey if they had had the forethought and had taken the time to reply. These persons, also, are usually the ones needing personal interviews.

A questionnaire survey, to be most effective, must be brief in its number of questions, and these must be carefully worded to produce the greatest amount of needed information, but be so clearly stated that but one interpretation can be given them. A long list of questions will be cast aside where a short list of pointed questions will be answered. A few important and definite replies from a large number of persons are of much greater value than a long list of questions answered by but few.

In a consideration of the replies to a questionnaire much depends upon the definiteness of the questions and the character of the persons interrogated. The viewpoint of the other person must be considered and due allowance be made. Even then the answers collectively apply to the writer's and not to the general average of all persons questioned or involved. Much valuable information can be obtained by this kind of a survey, but the answers are of greatest use when considered separately with a view of offering suggestions or making separate reports.

Study of Social Conditions

Many social and industrial conditions lend themselves separately as available for desirable surveys. Such surveys are for the express purpose of bettering existing conditions in the most practical and economical way. Completeness is essential and the survey must be sufficiently representative before deductions or recommendations

can be made. Before drawing his designs for a hospital, an architect studies the local surroundings and needs and then he surveys the experiences gained from the construction and operation of other hospitals, and adopts the details needed to fill the particular local requirements. A sanitary engineer must very carefully consider all local conditions before recommending a water purification or sewage disposal system if he expects complete success. His study is a sanitary survey of the points concerned in his undertaking and is a necessary part of his work. If such a survey is justified, health surveys in practically every branch of public health work are desirable and justifiable. These surveys may not be as extensive and expensive as house to house canvasses, but should be sufficiently detailed so as to show the true conditions and needs in their relative statistical importance and in their correct concrete perspective.

A study of conditions may be made by a correlation of statistical data, but a survey requires a certain amount of field work. If the subject for consideration is tuberculosis, a compilation of the case and death reports will indicate the prevalence of the disease and a spot-mapping of the cases will show their distribution and general locations involved, together with any tendency to group around industrial centers. The map will also indicate the approximate locations of needed dispensaries as well as of educational centers. But before a maximum result can be obtained, a district survey is needed to indicate local sanitary needs, the standards of living in the involved areas, racial and class characteristics, and the influencing factors of industrial employment. A canvass of the persons with tuberculosis will further elucidate the problems of prevention and control and will add much to the general survey. It will show the particular class of work which may have induced the development of the disease and also frequently will uncover unknown and uncontrolled cases of the disease.

A canvass of persons with tuberculosis by house visits will throw much light upon the factors and results of infection. It should be supplemented by clinical examination of every person in each involved family. The employment of each is studied with a view of discovering influencing factors and opportunities for transmission to other persons. In obtaining the address of the alleged employment it is important to learn the work done during the past several years, as the most recent may have had no effect upon inducing the development of the disease. It is not sufficient to know that the man worked in a machine shop, but what particular shop, the specific kind of work he did, the dates of beginning and stopping such work, and his own physical condition when he began the work should be learned. The names of other tuberculous persons in the mill should also be learned if possible. Fortified with this information, the investigator calls at the mill to determine every factor which could have been responsible for the tuberculosis; particular study is given to the other employees, the conditions of dust, of ventilation, of drinking cups, food supplies, general cleanliness, and habits of spitting.

Perspective is a particularly valuable adjunct to a survey. For instance, in the study of housing conditions, tenement factors form a vicious circle; and the landlord is not wholly to blame. The chief causes of unsanitary living conditions among our lowest classes—which form a truly dangerous condition for the general public in the production and transmission of disease, immorality, and degradation—may be written, according to cause, as: the penuriousness of the landlord; shiftlessness of the tenant; inherited instability of purpose; racial or social ignorance; disregard for people or property, developing from arrogance of superiors and their desire for large returns from uncertain investments; and the parsimonious habit of the property owner or his agent, who may be influenced by the absolute disregard and disrespect of some persons for the property of others. A housing survey in almost any city will show that these conditions obtain and that an improvement must be a general concession by all persons concerned, with a realization of the purposes and standards of the others. So in making suggestions in this, as in any other survey problem, the perspective must be studied to determine where the lines of force may coincide to an effective result.

Industrial Surveys Important

As applied to an individual establishment or class of industry, a health survey is a developed expression of a sanitary inspection. An inspection reveals the faults and needs; a survey correlates these facts and reveals influences.

Industrial establishments frequently need health surveys. Hygienic faults in industry are often commercial losses, decreasing the output and being a direct cause of labor unrest. A detailed survey may clearly indicate these economic and efficiency losses and show how they may be corrected. Every factory does not need a critical inspection, and in many in which a sanitary survey would be of benefit it would be difficult or impossible to prove the wisdom of the expenditure on the basis of expecting it to be more than

counterbalanced by the increased factory output. Employers are coming more and more to learn that the contentment of the employee is something to strive to maintain, and that the health of labor is worth considering. One factory manager told me that formerly when they held a grudge against a man he would be put at the emery wheels, where he would soon go down and out, but that now they conserved their experienced, trained help, considered now as worth retaining.

Industrial physicians, those who are employed in whole or on part time to care for the needs of the workmen, can and should make careful health surveys of their industrial plants or should use their influence to have the work done. Recommendations which are given the employers should be followed up by the factory physicians, who should find out what is being done and why. The effect of the alterations should be later reported to the person who made the recommendations and, if the improvements are not adopted, the reason for this inaction should be reported. It is not sufficient for an industrial physician to spend his entire energy in conducting a clinic for the sick and injured. Efforts should be taken to learn the causes of sickness and injury and to check or eliminate them. This is but a part of his opportunities for hygienic improvements. There are many other industrial factors which are not potent enough to produce sufficient sickness or accident to induce the workman to seek a physician, but are great enough to cause physical discomfort and to decrease personal and factory efficiency. These influences are determined by a close study of all the conditions under which the employees work.

Factors Brought Out in Survey

In industrial health surveys of individual factories cognizance is taken of every factor which directly or indirectly affects health. These factors include the conditions of ventilation, dust, lighting, water supplies, toilet accommodations, overcrowding of machinery, accidents, use of mill substances which may be harmful to workmen, habits of eating, provisions against fire and explosions, opportunity for and instruction in first aid, and social habits of the employees.

A factory health survey is made in conjunction with the investigation of industrial conditions affecting the production of some specific disease, as tuberculosis or one of the industrial poisonings, when one special mill or all the factories are inspected. Or an investigation may be made of one or more factories, considering them separately, for the purpose of studying every possible influence the factory can have upon the health of its employees and the freedom from the cause or transmission of disease by its product. In such considerations a factory is any place in which a number of persons are employed and in which any commercial article is manufactured or handled.

A detailed and carefully conducted survey of all health conditions will enable the health officer and factory physician intelligently to use their time and resources to the best advantage.

THE STOCK-TAKING OF GREAT BRITAIN'S HEALTH

BY OUR LONDON CORRESPONDENT

The Blue Book containing the report of a commission appointed during the war by the British Ministry of National Service to investigate the results of the medical examination of recruits under the Conscription Act has just been published. In this report is exhibited the result of a stock taking of the manhood of the British race at home for military purposes and it provides gloomy reading. It appears from an investigation of the figures given that 10 per cent of the men in Great Britain under forty years of age were found to be of such bad physique as to be totally and permanently unfit for any form of military service. These figures are disheartening and, if taken at their face value, would seem to reveal a degree of racial degeneration degrading in a country which has always prided itself on its public health service.

However, if these figures be probed closely, it will demonstrate the fact that there is room for the supposition that they constitute almost a slander on the nation. They are based on the medical examinations held between November 1, 1917, and October 30, 1918, or during the period when all the available manhood of the country was being swept into the army. Before that time millions of young men had donned khaki and their satisfactory physique is not denoted in these figures. In addition, of those who remained in civil life, the able bodied men left to carry on essential trades were not all examined. It is perfectly clear that the figures which show 10 per cent of totally unfit are misleading, and it also seems certain that if all the men of military age in Great Britain were examined now, after the ravages of war, much less depressing results would be obtained.

Still, when all has been said that can be said in extenuation of the figures in the report, it must be confessed that their significance is the reverse of reassuring. The resources of the man power of this country have been lavishly wasted and it is due to the circumstance that Great Britain has been an industrial country longer than any other and has allowed her population to live under bad hygienic conditions. Of recent years it has been personal and domestic hygiene at the root of the trouble, for public health in a broad way has been well looked after. It is now more a question of defective and inadequate housing than of anything, and, to a lesser extent, of trades in which insufficient regard is paid to the health of the worker. The object at the present time is not to point to the degeneracy of our industrialized nation, for this has been by no means proved, but rather to pick out certain particular evils and grapple with them energetically.

Miss Julia Lathrop, head of the Children's Bureau, has been formally requested to assist the new republic of Czecho-Slovakia in the organization of child welfare work along the lines followed by the Department in the United States. Her duties will keep her abroad until July 1.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M OLMSTED, R. N., *Editor*

THE ATLANTA CONVENTION

THE first Biennial Convention of the three greatest nursing organizations in the world ended in Atlanta on April 17. It was the twenty-fifth annual meeting of the National League of Nursing Education, the twenty-first annual meeting of the American Nurses Association, and the seventh annual meeting of the National Organization for Public Health Nursing. The nurses, numbering more than three thousand, discussed the present and future outlook of nursing with a spirit of enthusiasm, democracy, and business-like efficiency. For nine days meetings were held —morning, noon, and night—in the Tabernacle and the Auditorium, but, to the surprise of some of the Atlanta folk, there was no falling off in attendance. The delegates and visitors were there to learn and they steadfastly refused to think of the movies, the shopping district, or the charming country drives.

Although each of the associations had its own sessions, there were joint meetings in which they discussed matters of interest to all. In one of the general assemblies the Sheppard Towner Bill was indorsed. In another, the request of the American Legion for a cash bonus to be given by the Government to every participant in the great war, regardless of the length of service, was discussed, and resolutions were passed to the effect that the nurses are not in sympathy with the movement, that the men went into the War because they wished to be of use to the country, and not because of any desire for pecuniary reward. The associations are of the opinion, however, that those who were disabled in service should be given extra assistance.

For some time the National Organization for Public Health Nursing has had offices at 156 Fifth Avenue, New York City, and a branch office in Chicago. At the Convention in Atlanta, it was decided that joint offices of all three national nursing bodies should be established in New York City. This is a great advance and will, without doubt, result in better cooperation and greater efficiency in the future of the whole nursing profession.

Miss Katherine Tucker, president of the National Organization for Public Health Nursing, and superintendent of the Philadelphia Visiting Nurse Association, presided over the meetings of the public health nurses. The by-laws of the National Organization for Public Health Nursing were revised, the most important change being the striking out of the voting-by-mail privilege. This was accomplished after a very spirited discussion with arguments that showed considerable determination.

The rapid development of industrial nursing in recent years led to the formation of a separate section under the National Organization for Public Health Nursing, with the appointment of officers and the passage of resolutions. Separate sections were also formed in School Nursing, Child Welfare, and Tuberculosis.

The National Organization for Public Health Nursing, the only nursing body which admits lay members, included in its program a session for non-professional members, devoted to public health nursing administration. Special emphasis was placed on the need and proper management of nutritional clinics, publicity aids in public health nursing, newer fields of public health nursing, rural needs and rural problems, the protection of school children, and the recruiting of student nurses for the training schools.

The next convention will be held in Seattle in 1922, whose "booster delegates," vowed that Seattle could surpass any other convention city.

Miss Edna Foley, superintendent of the Chicago Visiting Nurse Association, was elected president; Miss Elizabeth Fox, director Bureau of Nursing, American Red Cross, Washington, D. C., first vice-president; Miss Jessie Marriner, Alabama State Supervising Nurse, second vice-president; and Miss Olive Chapman, director of nursing in the Mountain Division of the Red Cross Section, secretary.

RED CROSS PUBLIC HEALTH NURSING

By STELLA FULLER, R.N., Central Division, American Red Cross, Chicago, Ill

THE first step in the Red Cross Health program was the extension of the public health nursing service as now organized, and in operation under the Department of Nursing. This is a natural outgrowth of the work of the town and country nursing service begun some years ago by the appointment of a few score of visiting nurses for duty in rural communities.

The American Red Cross carries on this work through its Chapters and through affiliation with the nursing service of many local organizations; for example, boards of health, boards of education, county commissioners, industrial concerns, and public health nursing organizations maintained by private philanthropy or by a combination of public and private funds.

The Work Is Supervised

The Chapter or organization decides what work the nurse is to do; what the plan for the development of the work shall be; how it is to be financed, and all similar policies. The Bureau of Public Health Nursing maintains certain standards for the professional conduct of the work and, through correspondence, monthly reports from the nurse, and supervisory visits, oversees the Chapter work and its professional status. This supervision is done by the Division Director of Public Health Nursing, who tries in every way to advise the nurse and to assist her, should any difficulties arise.

It goes without saying that visiting nurses appointed by the Red Cross are at all times expected to act in full cooperation with other health agencies, and indeed the policy of the National office calls for the appointment of these workers only when other local organizations are not already providing such service. In order to meet the demand for specially trained nurses for this work, scholarships have been provided for nurses

Formerly the fight against disease was waged only upon its strongholds in congested districts. "Complete organization to cover the "whole field" is now the slogan, and health promotion is now directed against rural as well as urban problems.

The Red Cross nurse is ready for every emergency. This visiting nurse is seen making her daily rounds.
The young mother, perhaps untrained in the care of her children, welcomes the guiding hand of the public health nurse.

Demonstration is more effectual than words.

returning from war service, courses of instruction in this new science have been encouraged and used, and a number of chapters have liberally financed the preparation of nurses for this work. The Red Cross, therefore, counts on the development of a trained personnel to meet the greatly increased need for Public Health nurses. This indispensable foundation of expert professional service, coupled with the financial resources of an army of volunteers which the Red Cross can command, makes possible a powerful contribution toward the advancement of the public health work of the country to hitherto unparalleled achievements.

Service Is Many Sided

There is much variety in the work. A few of the nurses ride horseback over the mountain trails in the Kentucky mountains to care for their patients. Four or five go on snowshoes through the northern forests to the scattered homes and schools. Some with automobiles work up traveling clinics to secure eye, nose, throat, and dental treatment for their school children. Others are aiding in the Americanization programs in their daily visits in the homes of immigrant miners and laborers. Still others are helping to improve conditions for the workers in the Southern cotton mills, where they are employed as industrial nurses. Many are waging the tuberculosis battle and helping to secure legislation for county sanitoriums. Some of them give nursing care to the sick and many, in addition to their daily visiting, spread the knowledge of public health by addressing meetings, working up exhibits, and assisting in all kinds of campaigns for community improvements.

The Department of Nursing of the Red Cross, through its class instruction, is helping women and girls to prepare themselves to give nursing care in their own homes and to learn something about food in its relation to health. The oldest and surely the most popular profession open to women is that of wife and mother; yet little if any systematic training is given women for home making. Young men learn scientific farming at agricultural schools; medical students spend years in preparing for a highly specialized profession; business men serve long apprenticeships before they are entrusted with their first "big deal," but the majority of girls marry with little conception of their future duties and practically no training to help them meet the heavy responsibility of wife and mother.

Courses in Home Hygiene

Knowledge of proper nutrition, of sanitation and hygiene and of elementary nursing procedures is now recognized as necessary for the maintenance of high health standards. Thousands of women have taken the Red Cross courses in home hygiene, the care of the sick, and in home dietetics. Through such training they have learned to shield their households from preventable disease, and, by intelligent sick-room methods, to hasten the recovery of their sick. For pupils desiring the Red Cross certificate in home hygiene and care of the sick, the course consists of fifteen lessons of about one and one-half hours duration each. One-half of each lesson period is ordinarily devoted to theoretical work and demonstration; however, if a certificate is desired, an examination consisting of both written and practical tests will be given at the end of the course.

A diet intelligently selected, prepared, and served is one of the chief factors in promoting health and efficiency. Great advances have been made recently in the science of dietetics or food in its relation to health, and the Red Cross wishes to put elementary principles of this knowledge at the disposal of every woman and girl in the United States. Malnutrition has brought about the death of more babies and mental retardation of more school children than perhaps any other cause.

The Red Cross course in home dietetics offers instruction in the fundamental principles of proper nutrition for the well and the sick. This course is taught by a Red Cross dietitian who is a graduate of a home economics college and may be incorporated as a part of school work. It consists of fifteen lessons. These are only a few of the activities of the Red Cross whose mission is mercy, kindness and charity.

KANSAS CITY NURSES MAKE REPORT

The Visiting Nurse Association of Kansas City has just issued its twenty-eighth annual report which shows that the twenty-six nurses of the Association made in the last year 42,732 visits to 7,337 patients. The Association is the only agency in Kansas City organized to give bedside care by graduate registered nurses to the sick in their homes, and to instruct the families in hygiene and nursing.

It is the purpose of the Association to make its service not only to minister to the sick, but also to make it a great factor for public health.

Total receipts of the Association for the last year were $36,301.71, and disbursements amounted to $29,394.01. The Organization had an endowment fund of $10,968.73 at the beginning of this year.

The officers of the Association are: Mrs. James E. Logan, president; Mrs. George T. Moore, first vice-president; Mrs. W. H. Chapman, second vice-president; Mrs. F. D. Whiting, secretary, and Mrs. F. P. Burnap, treasurer. Miss Anna M. Barr is superintendent of nurses.

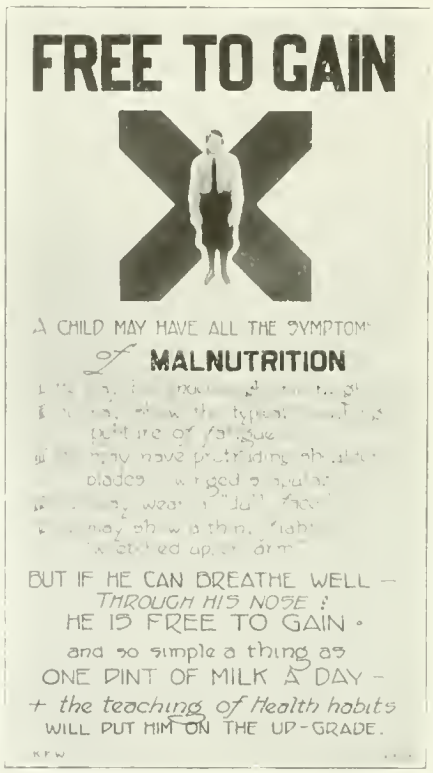
Human conduct tends to become not only more intelligible but more amenable to control as we view it in the light of an understanding of the instinctive mainsprings of action.—Ordway Tead.

NUTRITION CLASSES IN THE CHICAGO SCHOOLS

By MRS. IRA COUCH WOOD, Director, Elizabeth McCormick Memorial Fund, Chicago

Aside from all the dramatic incidents of the great war and the profound effect made upon the Nation by our share in the world conflict, several conditions directly affecting the welfare of the people in peace were emphasized by the war time program. Conspicuous among these was the poor showing made by our young men when measured by the physical standards of the Army, and the large percentage who were rejected for physical defects. No one doubts that if such tests had been made of our young women, even a greater percentage of physical defects and inefficiency would have been disclosed. These conditions found among the men of draft age were emphasized and partially explained by the weighing and measuring tests given during the war time program of the Children's Year, which showed such a large percentage of children under weight and handicapped by so many and such serious physical defects.

Thinking people have not been able to rest under the implication that the homes and the schools of this great democracy were somehow failing to produce men fit for the defense of the Nation in her hour of need, and many resolved that the health standards of peace should be at least raised to meet those of war. People wondered, many of them perhaps for the first time, why physical as well as mental and moral fitness should not be expected of the citizen as well as of the soldier. The challenge of the war, therefore, called into action many a supine health department in city and state, and started parents and educators, physicians and nurses, to work to rescue the children from a future of physical unsoundness, and to set their feet upon the road to health, happiness, and efficiency.



FREE TO GAIN
A CHILD MAY HAVE ALL THE SYMPTOMS
of MALNUTRITION
BUT IF HE CAN BREATHE WELL —
THROUGH HIS NOSE !
HE IS FREE TO GAIN •
and so simple a thing as
ONE PINT OF MILK A DAY —
+ the teaching of Health habits
WILL PUT HIM ON THE UP-GRADE.

The signs of malnutrition are evident enough and seen all too frequently once one begins to observe them.

The Elizabeth McCormick Memorial Fund of Chicago, having devoted itself to some solutions of the health problems of children since its foundation in 1908, carried on the program of the Children's Year in Illinois as its war service. Whatever may be said as to whether or not the weighing and measuring tests of the Children's Year were of any value as scientific records, they served as an efficient means of carrying educational propaganda throughout the country. Two results of this propaganda have proved of the greatest value: (1) People generally learned to their immense surprise that there are standards of physical development to which children should measure up; and (2) the tests proved that the problem of physical unfitness is not one of poverty, but of ignorance. They showed that the children of the rich and well-to-do were quite as undernourished and defective as the children of the poor. The answer to the problem, therefore, was to be education, and not economic revolution, as many had feared and prophesied.

The important question now became—what form should this education in health take to be most effective? This question had been partly answered, it is true, by the educational health programs already begun in some places through infant welfare centers, medical inspection in schools, public health nursing service in city and rural districts, medical and dental dispensaries, anti-tuberculosis propaganda, open air schools, and other agencies.

The Elizabeth McCormick Memorial Fund had made its contribution to these beginnings by maintaining twenty-three open air and open window school rooms in Chicago, and had proved what the triple program of fresh air, good food, and rest can accomplish. The majority of the anemic, or pre-tuberculous children, as they were formerly called, could in these classes be brought up to a normal physical standard, and most of them were enabled to make more rapid progress in their school work than would the children in the average school room. It was still true, however, that some children failed to gain sufficiently, and others lost their gains after leaving the particular school.

Aroused by the findings of the Children's Year for the pre-school age, and continuing its interest in the physically handicapped child, the Memorial Fund undertook in the winter of 1919 to estimate the amount of malnourishment among pupils in the Chicago schools by weighing and measuring ten thousand children. The relation of weight to height is the best test yet available to determine the physical development of children. Of the 10,000 chlidren weighed and measured, 5,045 were carefully tabulated and 40.5 per cent were found to be 7 per cent or more under weight. Dr. Thomas D. Wood's table was used, the basis being the average weight for height—not age. These schools were typical of different sections of the city, of different racial groups, and of varying degrees of prosperity in the several neighborhoods. The study included children from four years of age up, and in all grades from the kindergarten through the eighth grade. The percentages ranged in different schools from 16.2 per cent of the children showing undernourishment in one school in the stock yards district, to 57.7 per cent in a comfortable, semi-suburban neighborhood.

After these tests had indicated the seriousness and extent of the problem of malnutrition in Chicago, the attention of the Memorial Fund was directed to the work of Dr. W. R. P. Emerson of Boston, through a talk given by him at the International Child Welfare Conference in Washington last spring, which was illustrated by pictures of the children he had helped. The practical and intensive methods of the nutrition class, as developed by Dr. Emerson, seemed to be the answer to some of the unsolved problems of most of our health programs. The Memorial

Fund, therefore, brought Dr. Emerson to Chicago to speak at the sessions there of the International Child Welfare Conference, and his report and pictures made a profound impression upon educators and social workers.

Under Dr. Emerson's direction, nutrition classes were instituted in several Chicago schools last fall, and in November Dr. Emerson and his chief nutrition worker, Miss Mabel Skilton, came to Chicago and conducted a two weeks training course for forty-five students. This course gave great impetus to the work, and demands by different groups for nutrition classes have steadily increased. The Elizabeth McCormick Memorial Fund has added worker after worker to its staff to meet this demand, until now it has eight nutrition workers and one medical adviser.

These nutrition teachers for the most part are dietitians, as it happens; nurses would have had equally good educational background, but they have not been obtainable. All the workers have had sound preliminary education, have taken courses in food values, and social service, and have been given special training in the conduct of nutrition classes. These methods of Dr. Emerson, while they are simple, as fundamental principles always are, are founded on sound psychology and a sympathetic comprehension of child nature, and they demand special training and fitness on the part of those who are to use and develop them. Absolute accuracy is essential on the part of the worker; also painstaking attention to the smallest detail, and a great enthusiasm for positive health.

This is a typical case of malnutrition, exhibiting the slouching "posture of fatigue."

The Work Is Cooperative

In Chicago the Elizabeth McCormick Memorial Fund has had the approval of the Board of Education and the superintendent of schools in establishing nutrition classes. These are never started in a school without the complete and sympathetic cooperation of the principal, who invariably requests the Memorial Fund to start the work among the pupils. All the children in the school are weighed and measured, and those *habitually* 7 per cent under weight for height, who have also the unmistakable signs of malnutrition, are selected for the classes. The usual signs are—circles under the eyes, bad color, winged shoulder blades, frequently spinal curvature, sunken chest, prominent abdomen, stringy forearm, slightly flexed knees, and general "fatigue" posture. These signs for the most part escape the notice of the school physician and are not "diagnosed by the stethoscope," to quote Dr. Emerson, as the child's heart and lungs may be sound. Therefore, the first move after the weighing and measuring, is to give every child a complete physical examination, stripped, with the permission, of course, of the parents, and their presence at the examination if by any means this may be secured. The findings are checked off by the nutrition worker, with the parents' observation, on a form prepared by Dr. Emerson, which is much more detailed and specific than such forms usually are. This form is of great value in calling the attention of the examining physician, the nurse, or the nutrition worker, to the small points to be noted. After the examination, a large chart, 19 by 24 inches, is prepared for each child. It carries all the particulars of age, height, weight, average height for age, and average weight for height, pounds and percentage under weight, and has the average rate of gain carefully plotted and indicated by a black line. The child's actual weight is shown by a red line and large red dots, marking his gains or losses in the climb to normal standard. Red stars at the top of the chart indicate the mid-morning and mid-afternoon lunches, and blue stars show the rest periods. A gold star marks the chart of the child who has gained most weight during the week. This "color scheme" is important as appealing to the child, and makes the chart more graphic to his parents.

One of the cleverest devices of Dr. Emerson's to stimulate the competitive spirit among the members of the class is placing the charts in the order of gains in weight, and seating the children in the same order, each opposite his chart. The presence of the parents is a vital part of the program, and they are seated in the same order, each behind his own child. Consider the effect on the pride of the parent who, with his child, sits week after week at the foot of the class! This is a stronger argument than tongue or pen could urge, and after a short experience of this kind the physician's orders—previously unheeded perhaps—begin to be followed. Tonsils and adenoids come out with parental approval, the "movies" are given up, coffee and tea are discarded, and the diet changed to bring the child (and his parent) to the coveted position at the head of the class!

The rate of gain indicated on each child's chart is based on the average gain of the school child, which is one-half a pound a month. In figuring averages and percentages of under weight the Boas and Burke table of weights and measures is used. It is expected that the undernourished children in the nutrition classes will gain at least one-half a pound a week, or at the rate of 400 per cent above the normal gain. Many of the children in the classes far exceed this expected result and gain as much as a pound to a pound and one-half a week.

These boys show all the signs of malnutrition. They are under weight for height, have winged shoulder blades, sunken chest, prominent abdomen, and slight spinal curvature.

The classes meet once a week, which has been found to be the best interval. The children are weighed by the nutrition worker and the charts filled out before the physician arrives to conduct the class. Each child gives the nutrition worker a forty-eight hour record of his activities and the exact amount of food taken during the forty-eight hours. This is figured in calories and the children not only do this easily but greatly enjoy the reckoning. The nutrition worker goes carefully over this record, checking the total number of calories taken each day, the average of which is placed at the bottom of the nutrition chart. Special points are noted which must be called to the attention of the physician or the child's parents. The physician and the nutrition worker spend comparatively little time with the children who have gained at the proper rate, except to approve and encourage them in their efforts, but give careful thought and care to the children who have not gained.

This girl will respond readily to the methods of the Nutrition Class as soon as her physical handicaps of bad tonsils and adenoids have been removed.

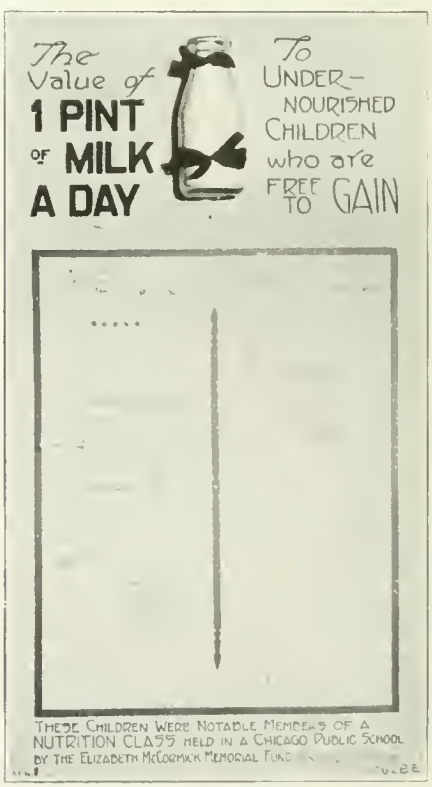
The nutrition worker suggests the proper diet for the children, including, of course, an insistence on milk, cereals, fresh vegetables, and fruits; but the foods with high caloric values are the ones most needed by the undernourished children who are to be started on the up-grade to health. Dr. Emerson's advice has proved eminently sound in recommending that racial prejudices be considered in prescribing foods, and that the line of least resistance be taken first in retaining everything that is good in the diet and suggesting additions to it rather than overturning the whole family scheme at once. It is necessary to win over the parents if a real readjustment in health and food habits is to be accomplished. Tact and persuasion will succeed, when backed up by the gains of the children, where argument and threat will fail completely.

Dr. Emerson has proved that for the undernourished child five smaller meals are better than three heavy ones, consequently a part of the program for the children is a mid-morning luncheon of milk and a graham cracker, or a sandwich of bread and butter or peanut butter, and another lunch in the middle of the afternoon. Lunches of this character do *not* take away the child's appetite for the noon meal; if sweets are given, however, this deplorable result will occur. The mid-morning and mid-afternoon luncheons should be followed by a rest period of three-quarters of an hour to an hour in the morning, and twenty minutes to one-half hour in the afternoon. These rest periods are of the greatest importance in the whole scheme and are especially valuable for the nervous, overstimulated American child. It is encouraging to know that once a child has been brought up to normal weight he tends to maintain his gains and develop normally, because nutritional balance has been secured, physical defects removed and health habits have been established.

Social Conditions Investigated

After the nutrition worker has absolutely exhausted her intelligence and ingenuity in discovering the cause of lack of gain, or the positive loss of weight on the part of a child, and after visiting the home to discover what social conditions may be affecting him, without finding a solution, the physician is then called upon to give the child a reexamination, in case something may have been omitted in the first survey. Too much cannot be said for the absolute necessity of having a sound medical background for all of the nutrition work because, while the normal standard of weight and health is usually attained by simple means, the causes of malnutrition may be obscure, and only medical science can then discover them.

Dr. Emerson's painstaking and scientific experience of twelve years' work with children has made him assign the following reasons for malnutrition: (1) Physical defects, especially obstruction of the breathing passages; (2) Lack of home control, the disorganized family, both rich and poor being examples; (3) over-fatigue; (4) insufficient food and faulty food habits; (5) bad health habits. These reasons, well founded as they are in wide experience, are certainly a challenge to all our preconceived notions as to the causes for undernourishment of children, and they suggest new and encouraging methods of attack on the problem.



The Value of
1 PINT
OF MILK
A DAY
TO UNDER-NOURISHED CHILDREN who are FREE TO GAIN
THESE CHILDREN WERE NOTABLE MEMBERS OF A NUTRITION CLASS HELD IN A CHICAGO PUBLIC SCHOOL BY THE ELIZABETH McCORMICK MEMORIAL FUND

This chart shows what a pint of milk a day, plus general health education, will accomplish.

At the present time the Elizabeth McCormick Memorial Fund is maintaining nutrition classes in eight elementary public schools, the Board of Education providing a physician and three visiting teachers to maintain others. So

interested have many of the school principals become in the gains in weight and increased mental alertness of the pupils in the nutrition classes that in some cases they excuse the children at 10:30 to return home for the mid-morning luncheon and rest period, the children returning for the short afternoon session. For the children in some of the other classes milk is provided from a special fund, and the rest period is taken at the school. When the school can thus cooperate with the home in the physical and mental development of the children, an ideal situation is created.

Very interesting nutrition classes are maintained in three high schools of Chicago by the Memorial Fund. These classes were started by three physiology teachers who heard Dr. Emerson and were inspired with the almost unheard of determination to demonstrate their science and test the practical result of their teaching through the physical development of their students. Complete physical examinations were given to these young boys and girls, and the pictures presented of physical deficiency were truly appalling. The children in these classes come from comfortable homes for the most part, where the parents are able to give their children the educational opportunities the high school affords. Some of them come from very well-to-do families, but the physical condition is uniformly poor, the underweight for height in many cases ranging from 18 per cent to 33 per cent in different individuals. These young people are now making satisfactory gains and have sufficient stamina and determination of purpose to carry out the program prescribed for them in spite of the difficulties that arise, sometimes from lack of parental cooperation, frequently from the overcrowded school program, the brief period allowed for the noon lunch, and the work that must often be done at home in addition to the school requirements.

A child who has come up to the normal standard tends to keep his weight and continue to gain, if given a chance. The chart of a boy who went over the top in thirteen weeks at Arden Shore and was dismissed to go to work. His employer, who had become interested in the physical welfare of these boys, provided for him milk and occasionally a raw egg at 10 a. m. and 3 p. m. See the result of such interest! A future citizen has been put on the road to health—industry has gained an efficient worker.

Two classes are maintained by the Memorial Fund in a private school in a most favorably located suburb, where the parents are more than well-to-do, and of an intelligent —not to say intellectual—group, and yet where 25 per cent of the children were found to be under weight and malnourished. One class is maintained in a private home where the children have had every social and educational opportunity that wealth can afford, but where the percentage of malnourishment also ran high. This class has been maintained to emphasize the fact that the whole movement for the health of children should be educational and not charitable. Classes are being started among children on the lists of the United Charities, pensioners of the Juvenile Court and in one hospital dispensary.

One of the most interesting pieces of work in which the Memorial Fund is cooperating is that now being carried on at the Arden Shore Camp at Lake Bluff, Ill. This camp is usually maintained only in the summer, for mothers and children from our congested districts in Chicago, who spend a couple of weeks on the shores of Lake Michigan. The Board of Directors, however, was persuaded by the Memorial Fund to open certain of the buildings for the winter and take fifty boys at a time, selected from those coming to the Employment Certificate Bureau maintained by the Board of Education, to secure their working certificates. These children, the product of the homes and schools of the city, are many of them found to be very seriously handicapped by physical defects, and so large a percentage of undernourishment that they would not last more than a few months in industry. According to the wise provision of the Illinois Child Labor Law, their certificates must be refused, but this refusal offers no adequate solution to the problem, because the children return to the same home conditions and lack of care, the same poverty and ignorance that created their disabilities. Arden Shore Camp offers the way out of the maze to these boys, and many are eager to accept it. Before being sent to the camp the boys are given a complete physical examination by the Medical Director of the Employment Certificate Bureau. As far as possible, the physical defects are removed or relieved, so that the boys are free to gain. The Board of Education provides a physician who visits the camp once a week, and two teachers, one of them in charge of vocational work. The Arden Shore Association has raised sufficient funds to provide housing and administrative force for the camp, which includes a superintendent, supervisor for the boys leisure hours, a graduate nurse, a housekeeper, a cook, and one outside man. Dr. Emerson's program is followed to the letter, and the boys return in periods ranging from four weeks to three months, made over in a fashion that seems almost miraculous. A number of business men have become interested in this project of saving boys for a life of productive industry, and one employer was so concerned lest the boys he took into his service should lose their gains made at the camp, that he continued to provide the mid-morning and mid-afternoon glass of milk, with a few minutes of rest following, with the astonishing result in one case that the boy gained eleven pounds in three weeks in industry.

Interesting as is this experiment, the Elizabeth McCormick Memorial Fund is convinced that the place for the nutrition class is in the school, where the children naturally congregate, where parental cooperation can be most easily secured, and where a system of medical and nursing inspection should be adequate to have physical defects removed. In the school the nutrition class has a chance of being considered a part of the educational curriculum

and to take its place by right as more important than even the three "R's."

We believe the class method of teaching health and nutrition to be valuable for the following reasons:

(1) It secures the cooperation of the parents, vitally necessary if results are to be permanent, in a simple and effective way.

(2) It economizes time of all concerned by bringing parents to the center, and minimizes the necessity for home visiting.

(3) It introduces a wholesome spirit of competition among the children.

(4) It pools the experience of all the families for the benefit of each.

(5) It provides a means, through the graphic charts, of judging the development and gain of the individual child.

(6) It removes prejudices and fears of parents and children through exact knowledge of results obtained, and convinces in a moment where hours of arguments have often failed.

(7) It provides a method where children may be made well in their homes without adding to the family budget.

(8) It suggests a means whereby the educational, medical, and nursing departments of the school may cooperate to promote the health of the child, with no prohibitive expense.

Dr. Emerson has designated the Elizabeth McCormick Memorial Fund as a center in the middle West for the distribution of his literature, and demonstrations of his methods of conducting nutrition classes. He will himself be in Chicago several times a year to conduct training classes for nutrition workers, assisted by members of the staff of the Memorial Fund. The latter has just completed a course for forty public health nurses from the School of Civics and Philanthropy, and a new course under Dr. Emerson will start May 3.

Nutrition classes for children are of special interest to nurses as a constructive social movement for health, and as offering a new field for nursing service. It is work that demands rather a new point of view for nurses, however. Tuberculosis nursing, though health is the aim, is a campaign against a disease. In school nursing, also, the aim is health, but there is a definite set of foes to fight. In this type of nursing the aim is a nutritional balance, and it is necessary to have definitely in mind the normal child into which the underweight one should be developed by hygienic measures. This is sometimes difficult. We have so long thought in terms of fighting disease that to face about and build up pictures of health takes some mental readjustment. It also requires attention to some details that, in ordinary medical and nursing care of the child, are often entirely overlooked.

The Nutrition Class is, of course, but one part of the great health program which should operate in every city and village in our land; but it is a most essential part, and has proved its value already by the definite results achieved. Children have been saved from a life of physical unfitness which spells inefficiency, failure, and unhappiness, and have been well started on the way to health, joy, and success.

PSYCHO-ANALYSIS FOR THE MISSIONARY

A course has been instituted at Columbia University for the study of folk lore and of hereditary influences of the natives in the preparation of prospective missionaries to provide a knowledge of the customs, attitudes, and conditions of the peoples whose reactions he must interpret if he is to influence their conduct.

THE CENTRAL COUNCIL FOR NURSING EDUCATION

By MARTHA WILSON, Chairman, Executive Committee, Central Council for Nursing Education, Chicago, Ill.

A new organization has recently been formed by the lay boards of seven of Chicago's large hospitals, with an object, stated in the by-laws, as follows: "To disseminate information regarding nursing education and the achievements and possibilities of the nursing profession." The cooperating hospitals are: Presbyterian, St. Luke's, Michael Reese, Wesley, Evanston, Children's Memorial, and the Illinois Training School.

This organization opened an office March 1 in connection with the Chicago Collegiate Bureau of Occupations. An executive secretary will devote her entire time to furthering the object of the Council by addressing groups of high schools girls, teachers' organizations, girls' clubs, women's clubs, vocational conferences, farmers' institutes, and similar gatherings. She will arrange for dignified articles to appear in the public press and will supervise the details of such publicity as may from time to time seem advisable. She will travel through Illinois and neighboring states in the interest of the Council.

Membership in this Council is open only to organizations actively engaged in Nursing Education, and an annual membership fee of $500 is required of each cooperating organization. Further information can be obtained by writing to the secretary, Mrs. Ira Couch Wood, 6 North Michigan Avenue, Chicago.

Each organization is represented in the Council by four delegates, one of whom must be the director of nursing in that organization. The activities of the Council are directed by an executive committee composed of the officers, chairmen of standing committees, and two members at large.

The following executive committee has been elected to serve for the year 1920:

Miss Martha Wilson, chairman; Mrs. Mary Maltman Bass, vice-chairman; Mrs. Ira Couch Wood, secretary; Mr. Chauncey B. Borland, treasurer; Mr. William D. Allen, chairman Finance Committee; Miss Bena M. Henderson, chairman Credentials Committee; Mr. A. J. Pflaum, member-at-large; Mr. M. Haddon MacLean, member-at-large.

The Executive Committee has secured Katherine M. Olmsted as executive secretary.

The Central Council for Nursing Education is rapidly assuming an important place in the field of nursing. Since its active work was begun March 1, numerous hospitals in the central states have requested application blanks. These have been sent out, and Grant Hospital is the first hospital, outside of the charter members, to be admitted to membership.

Very attractive postal cards and sticker stamps bearing a photograph of the Italian statue of Florence Nightingale are calling attention to the fact that this is the Nightingale Centennial year. They also bear the slogan of the campaign to recruit nurses, "Know the Joy of Service—Be a Nurse," and the following stirring words: "The country needs 100,000 more nurses."

Reports of the shortage of nurses are coming in from all over the country. From all come the following: "State superintendents of schools are most enthusiastic about the work and are anxious to have talks given to their senior students on the subject of 'Nursing as a Profession.'" State Superintendent L. N. Hines of Indiana says: "What we want here in Indiana is a big supply of registered nurses who are high school graduates and who have as much other education as possible."

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

MEDICINE AND SOCIAL WORK

THE increasing recognition of health promotion as a fundamental in social work has been fully demonstrated at the New Orleans meeting of the National Conference of Social Work, which has just closed. The physician and the social worker are plainly getting together.

In the extensive program of the National Conference comprised in ten divisions; two, the Health and Mental Hygiene Divisions, were devoted entirely to health and nearly every one of the other eight divisions had one or more programs or papers on the medical and health aspects of social work.

The Children's Division had four papers directly on health. The Division of Delinquents and Correction had two papers on medical aspects and a joint session on mental hygiene. Public Agencies and Institutions had three full sessions, with seven papers on health topics. The Family Section had three papers dealing with community organization especially relating to health. The Industrial and Economic Problem Section dealt in formal and informal discussion with aspects of industrial health. The Local Community Division presented one paper and numerous discussions on health organization. The Division on the Foreign Born in America had a full session on the health problems of the immigrant.

Fully half of the entire program related directly or indirectly to the conditions which affect health. The earnestness with which these conditions were discussed made it evident that on the part of social workers the medical and health aspects of their work are fully recognized.

This constituted the final meeting of the Fifteenth Annual Conference of the National Child Labor Committee with the general subject for discussion of "The National Child Labor Committee at Work." Reports were received of recent developments in the field of child care and specific accounts were presented of work in Alabama, Kentucky, Michigan, Missouri, and other states. The newly established Department of Child Welfare in Alabama, regarded by experts as representing the type of constructive supervision American commonwealths are likely to undertake in the near future, was discussed.

FOR COMPARISON

So much publicity has been given to the report of the Medical Society of the State of New York on health insurance that we reprint the findings adopted by the Committee on November 9, 1919, and the resolutions adopted by the same Committee on July 26, 1919. We republish these summaries without comment for purposes of comparison.

Findings November 9, 1919

First.—There is no necessity for the institution of a scheme covering the major portion of the population of the state providing for the institution of contract medical practice on a colossal scale in order to furnish medical attendance and other services.

Second.—In those countries where this scheme has been in operation for many years, it has caused a deterioration in medical morale and medical service and its effect in this state would be the same, that is, a lessening in the quality of medical service.

Third.—In comparison with those countries where this scheme has been in operation the United States shows a more marked reduction in mortality rate, both general and as affecting maternal and infantile mortality rate. Apparently the morbidity rate under the scheme has doubled instead of being diminished in Germany and Austria since the institution of the social insurance plan.

Fourth.—There is danger of the scheme gradually undermining the functions so extremely valuable to the community at present subserved by the State Department of Health.

Fifth.—Owing to the paucity of accurate and unimpeachable data collected by means of an unbiased investigation, your Committee recommends that the Legislature

of 1920 be requested to appropriate a sufficient sum of money for the use of the Health Department, and such other departments in association with it, as it requires, for the purpose of making a survey of the state of New York to determine the amount and character of illness in its economical relation to the commonwealth.

Sixth.—If additional legislation is to be enacted, it should provide for a greater development of existing agencies for preventive medicine, together with the extension on a large scale of the present county and municipal functions for both preventive and remedial medicine, and it should make further provision for the inauguration of more widely extended utilization of the present institutional clinical facilities for the diagnosis and treatment of disease, in order to facilitate the access of the entire population of the state to modern methods in the practice of medicine.

Resolutions July 26, 1919

(1) Unless the great mass of the population, including workers and their dependents, are brought within the scope of the proposed Health Insurance Law, no material improvement can be effected in the organization of the medical profession, nor can the benefits of medical science be more widely and satisfactorily applied than by means now available. This Committee, therefore, holds that the insurance funds must furnish surgical, medical, and nursing attendance, and the prescribed treatment, not only to insured persons, but to the dependent members of their families.

(2) Believing that the rural population now receives inadequate medical attention, we recommend that agricultural laborers be definitely included among the compulsory insured.

(3) Domestic servants should be included among the insured.

(4) No health insurance plan can be regarded as satisfactory which does not make available for the insured persons an improved grade of medical service, including the services of competent consultants and specialists; specific provision should be made for consultants, and consultant services should be organized in some form of group diagnostic clinics.

(5) Hospital maintenance should be distinguished from medical attendance in hospitals; that it, the insurance firms should not be permitted to make inclusive arrangements with hospitals for maintenance plus medical services, but hospital maintenance and medical service in hospitals should be treated as separate items.

(6) It is essential that any health insurance bill should provide for payment for professional services in proportion to the service rendered.

(7) The capitation system of payment is opposed.

(8) The employment, by funds operating under any health insurance law, of attending physicians or surgeons on salary is opposed; there should be a single system and principle of payment applicable to all insured persons, whatever the character or kind of fund in which the insured persons may happen to be insured.

(9) The health insurance bills heretofore presented to the legislature have failed to provide for such an organization of the medical profesion as would make the voice of the profession effective in negotiating rates with the funds; in the opinion of the Committee, the most promising form of organization for this purpose is one in which the whole body of legally qualified practitioners in the state would have representation and voice.

(10) Provision should be made for dental, nursing, and laboratory service for the insured and for the dependent members of their families.

(11) In making provision for laboratory and research work insurance funds should deal with health departments as far as possible.

(12) Free choice among all legally qualified physicians and surgeons practising in the state, should be granted to the insured.

(13) Physicians practising under any health insurance law should have the privilege of refusing to care for an insured person.

(14) Rates of compensation for medical services should be readjusted at intervals not greater than twelve months.

(15) The participation of commercial or profit making insurance companies in health insurance under any state health insurance law is opposed.

(16) Funds should provide maternity care for insured women and for the wives of insured men.

(17) Fees for obstetric services should not be fixed by law.

(18) The use of the word "panel" to describe physicians rendering service under a health insurance law, thereby distinguishing and segregating certain practitioners or groups of practitioners is objectionable; in place of the word "panel" there should be some other appropriate designation for the group of reputable and qualified physicians who may elect to practise under the law.

(19) Except with the special consent of the State Insurance Commission, no physician in general practice should at any time undertake the care or treatment of more than 500 insured persons with the dependent members of their families, unless it can be shown that there is not a sufficient number of practitioners in the district to provide one physician for each 500 families.

(20) For the purpose of facilitating the careful and deliberate organization of medical practice under any health insurance law, a period of not less than eighteen months should be permitted to elapse between the passing of the Act and the time of its enforcement.

(21) No medical officer employed by a fund for the determination of sick benefit allowances should be permitted to practise medicine in any capacity under the law.

(22) The qualifications of the medical officers of the funds should be prescribed by the state Civil Service Commission.

(23) Two additional State Industrial Commissioners, both reputable physicians, should be appointed for the purpose of administering any health insurance law.

(24) The Board of Directors of the several funds should consist of equal numbers representing the employers and the employees, and at least one additional director who should be a physician, and who should be chosen by a majority of the directors.

(25) There should be in all districts a medical office building to serve as a center where general practitioners and the specialists engaged in the treatment of ambulatory (insured) patients can do their work; these buildings should contain the proposed diagnostic clinics.

(26) It is proper that the state contribute a fixed percentage of the total cost of administering the proposed compulsory health insurance law.

To give men that portion of hope and illusion without which they cannot live, such is the reason for the existence of gods, heroes, and poets. During fifty years science appeared to undertake this task. But science has been compromised in hearts hungering after the ideal, because it does not dare to be lavish enough of promises, because it cannot lie.—Lesueur.

THE PROBLEM OF DISEASE*

From a Report by the Public Health Committee of the New York Academy of Medicine, New York City.

With the increased complexity of modern urban life, the problems of the treatment and prevention of disease have come to occupy a prominent place in the social policy of most of our communities. The hospital and dispensaries are beginning to realize their wider opportunities and responsibilities and in addition to social work they have taken on certain public health activities. The present time marks the beginning of a new phase of development in many directions and this part of the survey of hospitals and dispensaries was undertaken with a view to ascertain the prevailing usages and practices in the dispensary field and to suggest such changes in policy and procedure as would render the services of the dispensaries more effectual and perhaps more adequately adjusted to the demands made upon them.

We know that in New York City the dispensaries, outpatient departments of hospitals, and the Health Department Clinics treat very large numbers of people, more than one million annually, but what we do not know sufficiently well is to what extent the dispensary meets the problem of disease in the community. To obtain an approximate idea as to that, and, also, as to how the dispensary is being regarded by the people, the present fragmentary community survey has been undertaken.

In the course of the survey a door-to-door canvass was made of families residing in certain sections of the city selected in consultation with social workers, school teachers, and insurance agents. Information bearing on the extent of sickness at the time of the visit and during the year 1918 has been elicited, together with information bearing on the income of the family, length of stay in the United States, the ability to speak English and a few other factors likely to determine the course of action in meeting the problem of disease.

Name of Family Address Case No.

Unattended — Why

The appended schedule (Fig. 1) used in the door-to-door canvass, on which the information given by the patients when interviewed was recorded, will indicate the nature of the data which we endeavored to elicit and which constitute the basis of the present report. In the community canvass we visited 2,023 families whose domiciliary geographical distribution is as follows: 62.3 per cent in Manhattan; 7.9 per cent in the Bronx; 24.3 per cent in Brooklyn; 2.4 per cent in Queens; and 2.9 per cent in Richmond. (See Table I.) Of these families, 13.5 per cent were native born;[1] 22.6 per cent Italians; 16.3 per cent Hebrews; 17.6 per cent Slavs; 6.2 per cent Irish; 7.4 per cent Germans; 9.8 per cent Negroes; 6.6 per cent miscellaneous, including Scandinavians, Greeks, French, Scotch, English, Turks, and Armenians.

The districts selected were those in which certain racial groups were known to reside and in which there was not, as far as it could be known, any considerable proportion of destitute families. The aim was to include in the survey as large a number of self-supporting workmen's families as could be induced to give the desired information. Less difficulty was found in obtaining the information than we had anticipated. Only in few instances was refusal to furnish information encountered; whenever there was any disinclination on

*The second of a series of three articles on dispensary service appearing in MODERN MEDICINE.

1. As one of the aims of the study was to ascertain to what extent the existing differences in attitude toward illness and toward medical institutions are attributable to differences in racial habits and types of mind, the Hebrews and the Negroes were put in separate racial classifications, irrespective of whether or not they were born in United States. Likewise, all the Slavs were put in one group although there exist well recognized differences among them; and the Germans include natives of Austria as well as of Germany.

the part of the person to answer questions readily, the inquiry was not pursued. With the exception of the Germans, the majority of the families were ready to give the desired information. Some were eager to discuss their sickness experiences and to inform the Academy of Medicine about them in much greater detail than we cared to have it. In order to make the survey as representative of city conditions as feasible, we gathered the data in almost every section of Manhattan on both the East and West sides. We visited the Battery section; lower East Side; the lower West Side; the Chelsea district; on the West Side in the Seventies between Eightieth and Ninetieth streets and among the negroes in Harlem. In the other boroughs we tried to follow the same method but in a more restricted way.

Extent of Sickness in the Community

As has been stated, the families visited were asked as to illness in the family at the time of the visit as well as to the illnesses and their duration during the year 1918. Most of the studies of prevalence of illness are based on the information obtained at a point in time. This method is used because people know definitely about illness at the time of the visit, and the inquiring agent is able to observe conditions himself; while the information concerning the amount of illness during a considerable period of time is always inaccurate because a great deal of it is apt to be forgotten, particularly if it were of a minor nature or of short duration. Fully realizing that the information obtained for the past year would be inexact and rather under-estimated than over-estimated, we proceeded to obtain it; for, even though inexact, it would refer to a large amount of sickness and would throw more light on the question of provision made by families to meet the problem of disease than a mere cross-section at any given time.

In classifying the illnesses, the usual division into complete and partial disabilities was adopted. "Complete disability" designated a condition in which the person was ill for at least twenty-four hours and was unable to work or to care for himself. "Partial incapacity" was either an impairment of the usual ordinary activities or something for which treatment was taken. During the year 1918 there have been, according to this classification, 251 cases of complete incapacity per every 1,000 persons (Table II). This includes cases of influenza. If cases of influenza be eliminated, the number of complete incapacities per 1,000 per year would be reduced to 102; *i. e.*, barring influenza, there were *102 cases of some sort of complete incapacity during the year for each 1,000 persons.* As some of the individuals had more than one incapacity during the year, the average number of people per 1,000 having had some illness during the year is somewhat reduced. During the same year 157 cases of partial incapacity were found for every 1,000 persons.

The distribution of complete and partial incapacity by sex was as follows (Table III): Among the adult males there were 181 cases of complete incapacity per every 1,000 during the year 1918, inclusive of influenza cases. The rate of complete incapacity among females was almost double this figure, namely, 355 per 1,000. One reason for this wide difference between males and females is that cases of child-birth have been included among the complete incapacities. Eliminating this cause of disability, the rate for women was 203. Another probable, though much less important, reason for the difference is that in most instances the data about sickness were obtained from the female members of the families and they were more apt to remember their own illnesses than those of their husbands. The annual rate of complete disability for children under 16 was 225 per 1,000.

Among partial incapacities the variations are similar to the variations in complete incapacities. The lowest rate was found among the adult males, 128 per 1,000; the rate was 186 for adult women and 158 for children under sixteen.

The rates of prevalence of disease in point of time were of course much below the annual rates. The general rate of complete incapacity was 22 per 1,000. It was again lowest among the adult males, being 14 per 1,000; a little higher among children under sixteen, who showed a rate of 18 per 1,000; and again very high for females, 35 per 1,000. Here again the rate for women is slightly enlarged by the few cases of confinement found at the time of the visit. The general rate of partial incapacity has been found to be 50 per 1,000; 30 among adult males; 63 among females; and 55 among children. The rate of partial incapacity at the time of visit was more than twice as great as that for complete. For the illnesses during the year 1918 the complete far exceed the partial incapacities. This proves that in stating their illness experience people fail to remember a great many of the minor ailments.

Table I.—Racial Groups Included in the Community Canvass Tabulated by the Boroughs in Which They Lived

Borough.	U.S.A.	Italian	Hebrew	Irish	Slav	German	Negro	Miscellaneous	Total No.	Total Per cent

A Profitable Comparison

It is interesting to compare the complete incapacity rate found among the people at the time the canvass was made, that is, in January, February, and March of 1919, with the rate as ascertained in a canvass made by the Metropolitan Life Insurance Company jointly with the Chelsea Neighborhood Association of New York for the district between Fourteenth and Forty-second Streets, Fifth Avenue and East River in April, 1917. At that time the rate of complete incapacity per 1,000 was found to be 14.8 for the district. The higher rate found in our broader survey is probably due to the influenza still lingering at that time and to the greater exhaustion of the people in the period immediately following the stress of the war

TABLE II.—TOTAL NUMBER OF PERSONS INCLUDED IN THE CANVASS: NUMBER FOUND ILL AT TIME OF VISIT AND NUMBER ILL DURING THE YEAR—TABULATED BY NATIONALITY, AGE AND SEX. (NEW YORK CITY.)

time endeavors. Comparing our complete incapacity rate with other communities as reported in the surveys of the Metropolitan Life Insurance Company, we find the former to be considerably lower than in some other cities. For example, Kansas City showed a rate of 25.2; Rochester, N. Y., 23.1; Trenton, N. J., 25.8; North Carolina, 28.5.

The rate of distribution of complete and partial incapacities among the boroughs of the city in point of time shows marked differences. In view of the fact, however, that we made comparatively few investigations in the boroughs of Richmond and Queens, the rates for these boroughs are entirely inconclusive and therefore have been omitted.

Boroughs	Complete Incapacity Rate	Partial Incapacity Rate
Manhattan	15.3	48.8
Bronx	26.0	30.1
Brooklyn	30.1	64.0

A similar borough distribution of incapacity rates for year 1918 will show the following variations:

Boroughs	Complete Incapacity Rate	Partial Incapacity Rate
Manhattan	220	191
Bronx	304	128
Brooklyn	237	102

The distribution of the disability rates among the various racial groups of the population is particularly instructive. (Table IV). While the general complete incapacity rate in point of time was 22 per 1,000, it was 25 for the native born; 25 for the Italians; 30 for the Irish; 28 for the Slavs; 19 for Hebrews; 17 for Negroes; 15 for the miscellaneous group, and only 3 for the Germans. The rates among the respective nationalities for partial disability follow in a different order. While the average rate for the partial disability was 50 per 1,000, it was 55 for the native born group; 28 for the Italians; 104 for the Irish; 78 for the Slavs; 25 for Hebrews; 36 for Germans; 56 for Negroes; and 79 for the miscellaneous group. The groups that seem to have the largest amount of illness are the Irish and the Slavs, and the lowest prevalence was found among the Italians, Hebrews, and Germans. One of the surprising findings is that the prevalence of disease among Negroes is lower than among the native whites. It must be remembered, however, that while the Negroes in this survey were from among the better or more prosperous class, the native whites included in the survey and residing in the rather poorer districts of the city, are hardly typical of the average native population.

A similar tabulation of the prevalence of disease for the year 1918 gives the following results:

National Group	Complete Incapacity Rate	Partial Incapacity Rate
Native Born	230	301
Italian	309	83
Hebrew	255	117
Irish	183	302
Slav	277	112
German	152	206
Negro	134	174
Miscellaneous	231	225
Average	251	157

The rates based on the annual incidence do not fully corroborate the other findings. Although here, again, the Slavs show a high rate of incidence of complete disability, the Irish are below the average, and the Hebrews and Italians are in the highest groups. The Negroes again show a very low rate of complete incapacity.

Disease Distribution by Sex

A study of the rates of disease prevalence of each nationality by sex shows that illness is much more common among the women of every racial group. The differences in the rates between men and women are in some instances very high; for instance, in the native born group, where the complete disability rate for a point in time was 35 for women and 7 for men; and among the Italians, where the rate was 46 for women, and 19 for men. Among the Irish it was 54 for women and 15 for men, and among the Slavs, 58 for women and 15 for men. Only in a small measure is the difference due to incapacity on account of childbirth.

The difference in prevalence of disease among women of various nationalities is likewise very pronounced. It varies from 58 among the Slav women, and 54 among the Irish women, to 35 among the native born, 19 among the Negro women, and 6 among the German women. The variation of prevalence of illness among the men is much less noticeable. Here it is highest among the Negroes, reaching the figure of 21, and lowest among the native born, 7, and the Germans, 5.

The low figures for the German group throughout are probably due to the fact that on account of war conditions the Germans were suspicious and least willing to give any information about themselves. What has been said about the differences in the prevalence of complete incapacity applies as well as to the partial incapacities.

With a view to ascertain whether there is any relation between prevalence of disease and economic status, the

average weekly income per person in each family has been used as an exponent of economic well-being. A child under sixteen was, for purposes of tabulation, considered as half a person. Older children who were contributing only part of their earnings to the family budget, and boarders, were also considered as half persons in the figuring of the *per capita* income, since only part of their living expenses came out of the total family income, clothing and incidentals being paid for by them out of their own incomes. The total income of each family was divided by the total number of persons in the family, and in this way a *per capita* weekly income has been arrived at. It was considered inadvisable to employ more complicated statistical methods to arrive at the average weekly earnings per capita, such as were for instance employed by the United States Bureau of Labor Statistics in its recent study of family budgets.

As the wages during the year 1918 were uniformly high on account of the war demand for labor and, as the law prohibited persons from being idle, the amount of unemployment was at a minimum. The weekly wage ascertained at the time the inquiry was made has been taken as a representative wage for the whole year 1918.

Our 2,023 families were divided on the basis of the *per capita* income into seven groups. In the first group (A) in which the average weekly *per capita* income was less than $4.50, there were 166 families. In the second group (B) averaging from $4.51 to $6.50, there were 488 families; in the third group (C) averaging from $6.51 to $8.50, 475 families; in the fourth group (D), averaging from $8.51 to $10.50, 331 families; in the fifth group (E), averaging from $10.51 to $15.50, 253 families; in the sixth group (F), averaging from $15.51 to $20.50, 57 families; in the sixth group (G), where the average *per capita* weekly income was more than $20.50, there were 32 families. For 221 families, sufficiently definite information could not be obtained to warrant the figuring of the *per capita* weekly income. From Table V it will be seen that 8.3 per cent of the total number of families were in the lowest economic group, and that 14 per cent of the total number of Italian families were in that group. The native born and the Negroes each had 8 per cent of their families in that group, while the German and miscellaneous groups were represented in that economic division only to the extent of a little over 3 per cent each. In the second group, into which 24 per cent of all the families fell, the Italians had 29 per cent, the Slavs 27 per cent, Hebrews and Irish 26 per cent each, while the Germans had only 12 per cent. In the third group, $6.51 to $8.50 *per capita* income per week, there were almost 24 per cent of the total families; with the exception of the rather small percentages of Negroes and Irish, the remainder of the nationalities were in this group from about one-fifth to a little less than one-third of their families.

The first three economic groups contain more than 56 per cent of the total number of families. These three groups comprise more than one-half of the families of the native born, Italians, Hebrews, and Slavs; while the Irish, Negroes, Germans, and miscellaneous nationalities preponderate in the four highest economic groups.

As the number of persons in each family was an important factor in determining the economic status in our classification, the average size of the families of each of the nationalities may serve as a guide to the extent to which their economic status was either depressed or elevated by the averaging method employed in this study. By analyzing the data, we find that while the average family among the native born consisted of 4.1 persons, and that among the Italians it was 4.7, the Hebrews 4.7, the Slavs 4.8, the miscellaneous group 4.0, it was only 3.7 among the Germans, 3.5 among the Irish and 3.1 among the Negroes. The Irish and the Germans are the older immigrants; their average age is accordingly higher than that of the more recent immigrants, and the number of dependent children correspondingly smaller; hence other conditions being equal, their average *per capita* income strikes a higher figure than that of the other families having a larger number of dependent children. This also undoubtedly accounts for the fact that more than 50 per cent of the German and Irish families were among the four higher economic groups. The small average size of the Negro families included in this survey caused the favorable economic distribution presented by them.

Table VI presents the distribution of partial and complete disability for the year 1918 among the families classified by economic status. It shows that the lower the economic group, the higher is the percentage of families affected by illness. Disregarding the two highest economic groups, for each of which the number of families is comparatively small, we find a descending percentage of illness as the families ascend on the economic scale. Of the families with less than $4.50 *per capita* weekly income, 85.5 per cent had some illness during the year, as compared with only 68.4 per cent of the families in the fifth group (E) enjoying an income of from $10.51 to $15.50 *per capita* per week.

STUDENTS' HEALTH SERVICE AT THE UNIVERSITY OF CALIFORNIA

By ROBERT T. LEGGE, M.D., F.A.C.S., Professor of Hygiene and University Physician, University of California, Berkeley, Cal.

THE University of California, at Berkeley, now the largest university in the United States, pioneered the movement for a students' health service about fourteen years ago. My predecessor, the late G. F. Reinhardt, M.D., inspired with the principles of socialized medicine, and with several years' experience in physical education behind him, realized that the development of an efficient, scientific organization for the protection and conservation of the students' health necessitated the provision of a dispensary and hospital on the campus, and also the organization of a department of hygiene which could offer courses in health subjects and cooperate with the other academic departments whose activities were directly associated with health problems, such as physical and military education. Like all other pioneer movements, it required a great deal of energy and educational propaganda to remove the many obstacles to the consummation of a new measure of this kind.

First University Health Service

An old residence was secured and remodeled as a temporary infirmary to quarter the dispensary and hospital service, and so was born the first university health service. From the very inception of the organization, compulsory physical examinations and vaccination were instituted. A two-unit course in personal and community hygiene had already been made compulsory for the first semester for all freshmen. It was in this course also that students were made acquainted with the necessity for the control of communi-

A residence was remodeled to house the infirmary, and to quarter the dispensary and hospital service of the University of California, at Berkeley, which was the first university health service in the United States.

The waiting room is spacious and comfortable and carries little that is suggestive of the usual dispensary environment. Educated to secure scientific care before a serious condition develops, the students carry with them the message of preventive medicine to their homes and communities.

cable diseases, thereby eliminating, so far as possible, sickness as a cause of disability in university classes; for it was observed by the faculty that poor class attendance was principally due to this factor and not to lack of interest, or of idleness on the part of the students. The application of the value of "a stitch in time" could be demonstrated practically, for students could visit the infirmary and be scientifically treated before a more serious condition developed. With such an educational program, theoretically and practically demonstrated in a university community, our students could not help carrying the message of preventive medicine to their own homes and communities.

Time and time again students residing in boarding and fraternity houses, and taken ill with communicable diseases, caused the quarantining by law of those houses, thereby isolating the other inmates, non-infected and immune, and depriving them of attendance in their courses. Our private hospitals will not accept communicable diseases, so this was the only possible course. In struggling with such a situation the college infirmary provided a welcomed innovation to students and authorities alike. Whenever a student has been exposed to or is suffering from a contagious disease, he or she applies at the infirmary for admittance, advice, or examination. If the case, for example, by bacteriological and clinical examination is found to be diphtheria, all members of the patient's house must have nose and throat cultures taken so as to locate all missed and carrier cases. We pioneered the exposition of the principles that were laid down by Chapin in the hospitalization of communicable diseases, by practising medical asepsis. A special contagious building was never required, fumigation was abolished, and our records show no cross-infections have ever occurred. Concurrent and terminal disinfection is used, depending upon the type of infection, and advice is given to the patient when discharged. The fact that a system for the medical supervision of college students suffering from contagious diseases and providing for this isolation in a hospital could not be objected to by any fair-minded practitioner of medicine, formed the link of stability in our relations with outside physicians.

Only students who apply for service at the infirmary are treated. Under no circumstances will the staff treat or accept students as private patients residing outside the campus. Any student is at liberty to engage a private physician at his own expense if he desires, when ill at home, or for consultation with the staff when the case is in the infirmary.

Our teaching of hygiene régime involves the principle that disease is usually found in the sick and their duty is to avoid contact and so prevent others from being ill; and, when ill, to report their disease to the authorities and consult only legally qualified physicians for curative purposes. With an interest entirely destined to the prevention of sickness, to the decrease of academic losses and increased efficiency among the whole student body, the system has been approved by the leading medical men residing in proximity to the campus. Even among those cults opposed to health supervision no objections are offered when the work performed is in the nature of preventive medicine.

Physical Examination Rigid

Every student matriculating is obliged to have a complete physical examination, which is more rigid than the recent army standards required, as well as compulsory vaccination for those who

Main office opening into private office of the university physician. The staff is composed of nine men and women physicians, two dentists, two technicians, office clerks, and ten graduate nurses.

do not possess a satisfactory scar. Only in a few instances have applicants been denied admission, and these were advanced active cases of tuberculosis and mental disorders. How can any sane individual argue against physical examination when the advantages are so numerous, these including the recognition of early infections, the identification of missed cases and carriers, the finding of incipient disorders, the disclosure of congenital and postural defects, and the allaying of fear from imaginary illness. Besides these advantages, the physically weakened are advised to carry a limited amount of work ,as our slogan is "Health first." Mutual cooperation exists between the Infirmary and the Physical Education and Military Departments, the one physical examination record being sufficient. Many of our corrective cases for postural and pathological defects under medical prescription are supervised by the Physical Education Department.

The number of students who seek advice and treatment annually in the dispensary is between 50 and and 78 per cent. Why such a high percentage, may be asked, among such an apparently young group. It simply demonstrates the fact that the average person requires medical service and, when it can be easily efficiently administered, it supplies a very practical lesson in nipping the disease in the bud, thereby preventing a more serious condition.

Eye, ear, nose and throat room of the medical department at Berkeley. All students are treated in exactly the same manner, and whatever service is indicated is provided. The success of the method is a living demonstration of what mutual understanding and sympathy can accomplish.

As California has coeducation, the dispensary hours are arranged so each sex is treated at different periods, utilizing thereby all the facilities that are at hand.

The dispensary is not simply a place from which to deal out medicine, but a place in which the object is to determine by scientific means the underlying disease. This work on the part of the clinician, with so many students daily visiting the dispensary, would be impossible to handle if it were not for the complete history, with medical examination record, that always lies before him.

When the student applies he fills out a slip, takes a number designating his turn, and files same with the office clerk, who immediately seeks his record and forwards it by a mechanical carriage to the respective clinicians' room. The student waits in the waiting room until his number is called and is then dispatched to the nurse or doctor in the various treatment and consulting rooms. The rule is that if any applicant has 1° temperature the case is a hospital one for observation and development. Many a contagious case with only this one prodrome is safely isolated early. Each day as the records are returned to the office a statistical summary is made up according to a standard nomenclature of diseases, for the annual report. This procedure makes certain a correct diagnosis, when that is possible, and keeps the general record of the patient written up in recording the nature of the last visit.

The staff is composed of nine men and women physicians, two dentists, two technicians—a roentgenologist and bacteriologist—office clerks, ten graduate nurses, and the servants. The physicians give part time only; some are instructors in the Department of Hygiene, while the others enjoy outside practice. Of the staff, many are specialists, *viz.*, surgeons, oculist, orthopedist, urologist, and internists, the specialists devoting their time to their respective clinic hours and hospital service. With such facilities consulations are frequent and group medicine made possible. It is the primary purpose of the staff, through educational means, to teach the students how to live and eliminate disease by every available means.

In our experience we have discovered it is mistake to employ student nurses or medical students connected with the university, to treat patients, or to use students for clinical or demonstrative puposes. The university physician has definitely tried to aviod the "institutionalized spirit" by maintaining an atmosphere of warm personal interest about the place. The friendly advice of the physicians, the care, the good nursing, comfort and good food, the student avails himself of, without that feeling of dread so commonly experienced.

The Matter of Costs

As the state in its annual university budget does not make provision for students' health supervision, the fees are collected as a part of the

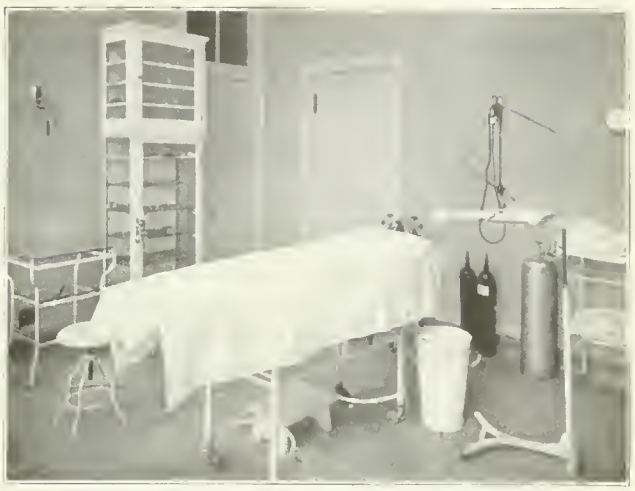
regular academic entrance fee. Of this amount, $3.00 *per capita* each semester is placed in the Infirmary budget. The University Physician is the administrative officer and is responsible to the President of the University. He also holds the position of Professor of Hygiene in the academic department.

At present the system provides for the fee, in addition to the complete physical examination and vaccination, dispensary, and hospital care, including food, shelter, medical, and nursing service, medicines, x-ray, clinical, and laboratory examinations. There is no extra charge except for special surgical operations and dentistry. A minimum fee is charged; for example, $50 for an appendectomy or mastoid, which includes complete hospital service. It is the avowed aim of the University Physician to eliminate these fees as ra idly as the funds will permit, particularly for such diseases as necessitate operative procedure and which occur during college residence.

All students are cared for in exactly the same manner, without distinction as to race, color, or creed. If a private room is required because of the nature of the disease, one is provided; if not, and a ward bed is indicated, the student is placed in a ward. Strict democracy is maintained a principal characteristic of the institution, a living demonstration of what mutual understanding and sympathy can accomplish.

For the house patients the Infirmary has sixty-eight beds which are in private rooms and wards. The private rooms are twenty in number and there are three large wards with a capacity of eight beds each. In 1918-19 the number of bed patients was 635; of these 69 were sick in bed as house patients more than once during the year, the average stay being 5.8 days. The average number of patients per day was 11.6 and the largest number at any one time was 40. The number of students who received advice or treatment during the past year (251 days), 1918-19, was 3,517, or 50 per cent of the total enrollment of 7,014 students. The average in normal years is about 72 per cent, with a daily dispensary numbering about 126 individual patients who average 7.8 treatments. The low percentage for the year 1918-19 was due to the fact that the Students' Army Training Camp cared for their own dispensary cases and the influenza epidemic victims.

Sixty-eight beds in private rooms and wards take care of the house patients of the University Infirmary. In 1918-19 the bed patients numbered 635, the average stay being 5.8 days, the average number of patients per day being 11.6.



The equipment at Berkeley provides the various features necessary for a first class hospital, such as X-ray laboratory, operating and sterilizing room, a splendid cuisine, open-air decks, a solarium, and numerous baths and showers.

Care for Incipient Conditions

To the uninformed it might appear that this large percentage of cases would indicate unusual morbidity; but, as a matter of fact, the purpose is to encourage early advice for incipient conditions, thereby avoiding graver complications and developments.

The equipment provides the various features that are necessary for a first-class hospital, such as an x-ray laboratory, operating and sterilizing room, a splendid cuisine where the best foods are supplied and prepared, open-air decks for the treatment of anemia and pulmonary cases, a solarium for convalescents, waiting rooms, and numerous baths and showers.

The estimate of costs for operating the infirmary was based on dividing the gross costs, which include salaries, the maintenance of dispensary and house service, by the number of beds, which gives an estimated cost per bed per day of $3.98. Surgical operations requiring anesthesia averaged about 150 *per annum;* X-ray examinations, 141; and clinical laboratory reports totaled 2,295.

As all students who matriculate are compelled to have a thorough physical examination, it enables us to inform them correctly as to their abilities for physical exercises, classroom work, or college sports. Numerous defects, focal infec-

tions, and occasionally graver conditions which might also jeopardize the health of others, and be a menace to the community, are detected and treated. Often students are relieved of imaginary diseases. In 1915 we found that 65 per cent of the freshmen had errors of refraction, and our oculist wrote seven hundred prescriptions for proper glasses. The dental examination one year revealed that only eighty-two men and fifty-six women out of the whole 1,513 entrant enrollment had normal teeth. Numerous other illustrations could be cited, such as postural defects, diseased tonsils, chest diseases, and flat feet. Enough has has been said the presence of remediable defects as an argument for compulsory medical examinations.

One of two dental service rooms at Berkeley.

These entrants must have a satisfactory scar to show that they are properly immunized against small-pox or submit to vaccination. This is a University law. Since 1901, when this law was established, there have been no cases of small-pox among the students. Typhoid inoculation is not a compulsory measure.

Our dental service was added five years ago, as it was proved clinically that focal infections were responsible for many illnesses among the student body. A first-class equipment was installed and two full-time dental surgeons added to the staff. A charge of $1.50 per hour is the fee exacted. This includes material and x-ray negatives. The popularity of the service is evidenced by the appointments which are booked sixty to ninety days in advance. In 1918-19 the statistical summaries recorded 1,785 fillings and 1,324 other dental operations—another triumph in preventive medicine.

With the establishment of a compulsory lecture course in personal and community hygiene, prescribed for all freshman entrants, where the truths of preventive medicine are taught and correlated with an institution whose staff of well trained medical men and women labor in harmony for the interest of the student body,—by this process of group study a definite contribution to the best type of curative medicine has been achieved. Certainly safeguarding the health of the students has been established through these agents at a great university on the Pacific Coast.

The cold treatment room is one of the provisions at Berkeley for safeguarding the students' health. Open air decks are provided for the treatment of anemic and pulmonary cases, and there is a solarium for convalescents.

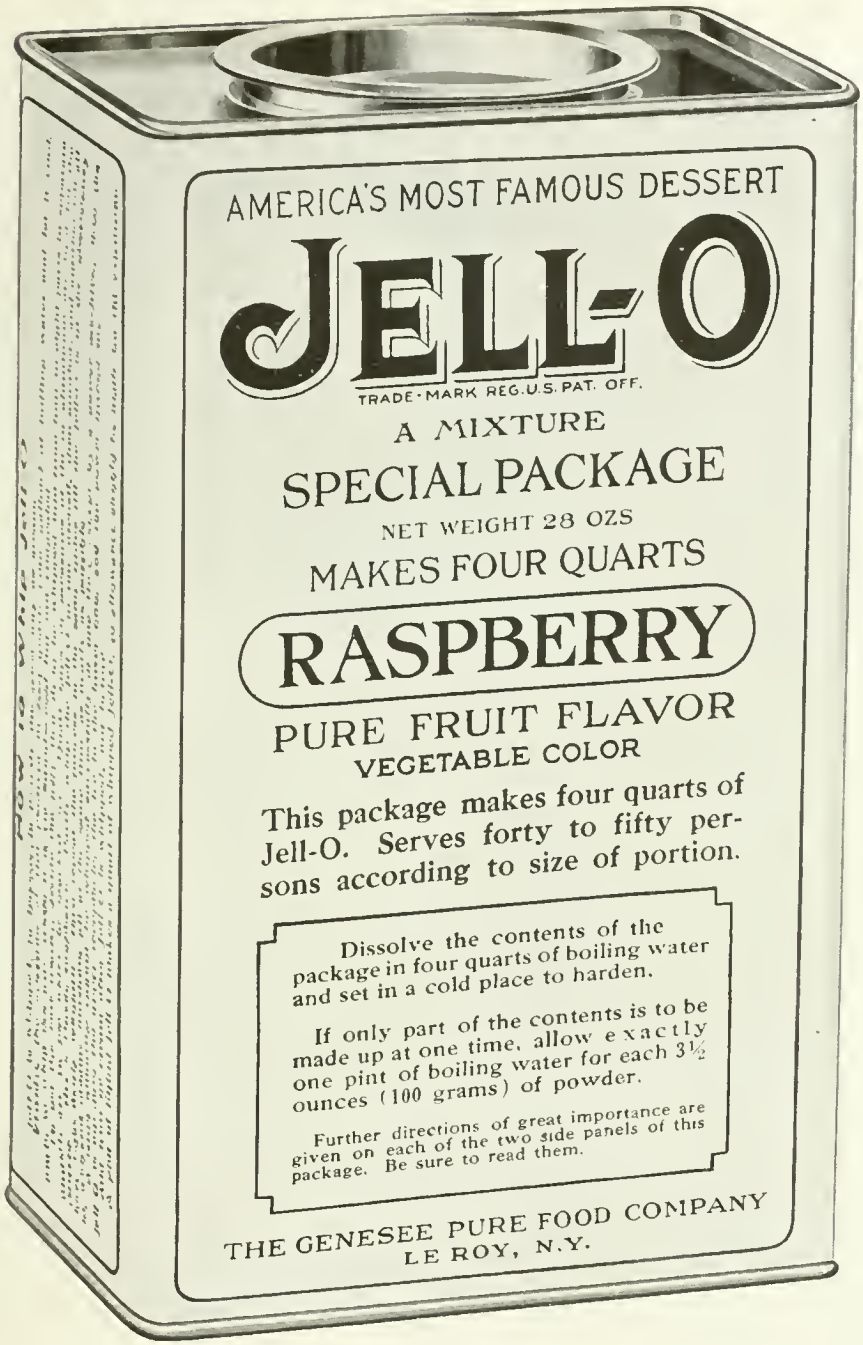
HEALTH CENTER IN NEW HAVEN

Announcement is made of the organization of the Health Center in New Haven, Conn., under the combined leadership and financial support of the four chief health agencies of the city, the Municipal Department of Health, the Visiting Nurse Association, the New Haven Chapter of the American Red Cross, and the New Haven Medical Association.

The Health Center will aim to build up the health as well as to detect the physical defects of the twenty thousand inhabitants in the selected district, whom are largely of Italian stock. Free medical examinations, nursing care in the home, and intensive educational work will constitute the main lines of activity. Medical treatment will not be given at the Center, but individuals will be referred to the abundant medical facilities of the city. It is expected that the Health Center will be in full operation by July 1. Its temporary quarters are 184 York street.

The Board of Control is composed of the following members: Prof. C.-E. A. Winslow, chairman; Mr. F. W. Wright, health officer; Mr. A. T. Hopkins, treasurer; Drs. O. J. Bartlett and N. Mariani of the Board of Health; Miss M. T. Dana and Mrs. L. M. Daggett of the Visiting Nurse Association; Mr. Thomas W. Farnam and Mrs. N. G. Buckland of the New Haven Chapter American Red Cross; and Drs. R. E. Peck and F. M. Sperry of the New Haven Medical Association.

The Executive Committee consists of the chairman of the Board of Control, Professor Winslow, the health officer, Dr. F. W. Wright, and the superintendent of the Visiting Nurse Association, Miss Harriet Leck. The director of the Health Center is Mr. Philip S. Platt, M.A., C.P.M., whose experience and training especially fit him for the enterprise.



AMERICA'S MOST FAMOUS DESSERT
JELL-O
TRADE-MARK REG. U.S. PAT. OFF.
A MIXTURE
SPECIAL PACKAGE
NET WEIGHT 28 OZS
MAKES FOUR QUARTS
RASPBERRY
PURE FRUIT FLAVOR
VEGETABLE COLOR
This package makes four quarts of Jell-O. Serves forty to fifty persons according to size of portion.
Dissolve the contents of the package in four quarts of boiling water and set in a cold place to harden.
If only part of the contents is to be made up at one time, allow exactly one pint of boiling water for each 3½ ounces (100 grams) of powder.
Further directions of great importance are given on each of the two side panels of this package. Be sure to read them.
THE GENESEE PURE FOOD COMPANY
LE ROY, N.Y.

The Easy and Sure Way For the Nurse

Among the dishes which the nurse likes to prepare are the refreshing and attractive salads of which the foundation is Jell-O. These are made by adding to the Jell-O chopped celery and bits of fruit and nutmeats. They are moulded in teacups or little moulds and each is turned out on a lettuce leaf.

Such a dish may be called a salad or a dessert and be very good as either. If served as a salad, Mayonnaise or other salad dressing goes with it.

As made of Jell-O, which contains all the ingredients that would have to be added if plain gelatine were used, there is a great saving of time and labor, and the result is always satisfactory. The nurse who uses Jell-O for her dainty dishes is never obliged to depend upon luck. She can easily and surely accomplish what she used to do with tedious detail and with qualms as to the outcome.

Jell-O is made in six pure fruit flavors: Strawberry, Raspberry, Lemon, Orange, Cherry, Chocolate.

The new Special Package for hospital use contains enough Jell-O to make four quarts of jelly as against one pint of the regular small size.

THE GENESEE PURE FOOD COMPANY
Le Roy, N. Y., and Bridgeburg, Ont.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRITPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

CONCERNING SOME HEADACHES AND EYE DISORDERS OF NASAL ORIGIN. By Greenfield Sluder, M. D., clinical professor and director of the Department of Laryngology and Rhinology, Washington University Medical School, St. Louis.[3]

The author has produced a work of enduring merit. He has treated some of the very vexatious problems of rhinology in a masterly manner. The non-suppurative diseases of the nose have been passed by, on the part of the average practitioner, as a necessary evil.

The book opens with an introductory chapter on the pathological anatomy by Jonathan Wright. Vacuum frontal headache is the subject of the second chapter. The material for this has been drawn from 580 cases. The author states that "eighteen years of observation of this class of cases leads me to believe Ewing's sign to be trustworthy." He also observes that the pain of vacuum frontal headaches is never as severe as that produced by suppurating sinus, that there is never any pus, never blindness, and never any change in the globe. The pathology and treatment are fully covered. In the chapter on the syndrome of nasal (spheno-palatine, Meckels) ganglion neurosis, the method of injecting the ganglion through the nose is described. Numerous case histories are recorded demonstrating points brought out in the text. The book contains a short bibliography.

A COURSE IN FOOD ANALYSIS. By Andrew L. Winton, Ph.D., author of "The Microscopy of Vegetable Foods"; reviser of Leach's "Food Inspection and Analysis"; translator of Hanausek's "Microscopy of Technical Products."[5]

This book, which is intended to serve as an introductory text in food analysis, has been written in a clear and concise style. The methods are selected judiciously and the descriptions are elaborate, but to the point. Some illustrations in the book are possibly superfluous. It stands to reason that a student who wants to follow up food analysis, and who has had a previous course in chemistry, knows how a Bunsen burner with a wire gauze cap looks, or how an iron mortar looks. Most illustrations, however, are very useful and help to illustrate the subject in question.

DISEASES OF NUTRITION AND INFANT FEEDING. By John Lovett Morse, A.M., M.D., professor of pediatrics, Harvard Medical School, and Fritz B. Talbot, A.B., M.D., instructor in pediatrics, Harvard Medical School, chief of Children's Medical Department, Massachusetts General Hospital.[8]

The book presents the various views expressed in literature on the metabolism of infancy and the diseases of infancy and childhood. Die Saüglingsernährung und Sauglingsoffwechsel, by Langstein and Meyer, served the same purpose for several years. However, this is the first attempt in English at a contribution of this character.

This book of Morse and Talbot is rendered the more valuable by virtue of the fact that one of the authors (Talbot) has done a great deal of experimental work on the metabolism of infancy and he is, therefore, well qualified to present a critical analysis of the work of others.

In the second edition of the book a number of references have been added and the literature has been brought up to 1918. The volume fulfills a want in American literature as a book of reference.

SOFOS

SOFOS is a product of the research laboratories of the General Chemical Company—one of the world's leading scientific organizations—a strictly American institution.

SOFOS Cuts Out Middle Reactions

Effervescent preparations of sodium phosphate usually contain citric and tartaric acids, which may not be entirely satisfied and form citrates or tartrates which in some cases are of doubtful or prejudicial action and effect.

SOFOS

contains only monosodium phosphate and sodium bicarbonate which effervesces on addition of water to form di-sodium phosphate and nothing else.

SOFOS is mild, pleasant and reliable in action.

SOFOS is agreeable and acceptable to the taste.

SOFOS does not gripe, "nag" or induce subsequent costiveness.

It is the ideal preparation for use in children, old people or debilitated or delicate persons.

Moreover, one part of SOFOS has almost double the phosphate value of the U. S. P. strength.

A clinical test of SOFOS will demonstrate, beyond question, the truth of its claim to be the most elegant, eligible and efficient preparation of sodium phosphate, at the disposal of the medical profession for whose use it is intended and will be ethically advertised.

SOFOS has been accepted by the Council on Pharmacy and Chemistry of the A. M. A. for inclusion in New and Non-official Remedies.

Ask your pharmacist for SOFOS. If he hasn't any, notify us.

DOCTORS GET LATE START IN LIFE

It was brought out at the Chicago convention of the Council on Medical Education that the average student completes his medical education at the age of twenty-nine. European medical training is scheduled so as to enable the practitioner to begin at the age of twenty-five. It is proposed to shorten the period of preliminary training in American medical schools so that it will not be necessary for a student to spend seven years in college and medical school before obtaining a medical degree.

SOME PRESENT DAY CARDIOLOGIC TOPICS

Suitable tests for cardiac efficiency have been the subject of special study for fifteen years, says Dr. Thomas E. Satterthwaite in the *New York Medical Journal* in a discussion of various tests. Dr. Satterthwaite objects to the use of strong drugs for diagnostic purposes, and emphasizes the difficulty of determining the normal energy-index.

For this reason the cardiologist, of all the specialists, is perhaps the most benefited by the scheme of having what is known as "group diagnosis." While this plan had been carried out for more than a quarter of a century in the wards of some of the large New York hospitals, it did not rise to the dignity of a regular feature of an institution until it was adopted by the Manhattan State Hospital for the Insane, on Ward's Island, in or about 1902, where complete diagnosis were made by a staff of paid specialists in every case admitted. The present scheme has three or four diagnosis clinics in operation in Greater New York. "Examinations and reports are made for physicians only, in each special department, and the combined results are furnished, together with the essential points in each case. . . . One may make the broad statement that thorough, comprehensive examinations can no longer be made by either specialists or general practitioners without help from their confrères. The field is now so large that no one man is competent to cover it properly," says Dr. Satterthwaite, "therefore diagnostic clinics, with 'group diagnoses,' have come and are going to stay."

PAN-AMERICAN ALLIANCE FOR PHYSICIANS

The original plan of the American College of Surgeons to include in its Fellowship all worthy surgeons of the American continents has been definitely promoted by the official visit by Dr. William J. Mayo, president of the College, and Dr. Franklin H. Martin, secretary general, to Peru, Chile, Argentine, and Uruguay. Everywhere these representatives of the American College of Surgeons were received with due regard for their mission. An interesting account of their itinerary is given in the current issue of *Surgery, Gynecology and Obstetrics*. Medical schools connected with national universities were visited at Lima, Santiago, Buenos Aires, and Montevideo. In general facilities, free beds, clinical material, and general requirements these compare favorably with the facilities of other countries. The mission was favored by meeting strong groups of each faculty.

A great desire was shown on the part of surgeons to cooperate and become affiliated with the College of Surgeons and in conference selected groups of eligible men were submitted, the published list containing the representative surgeons of Santiago, Valparaiso, Buenos Aires, and Montevideo. These men are characterized as "men of world vision" whose dread of narrow provincialism augurs well for a larger affiliation.

Six Popular, Council-Passed "Hits"

Chlorazene Surgical Cream

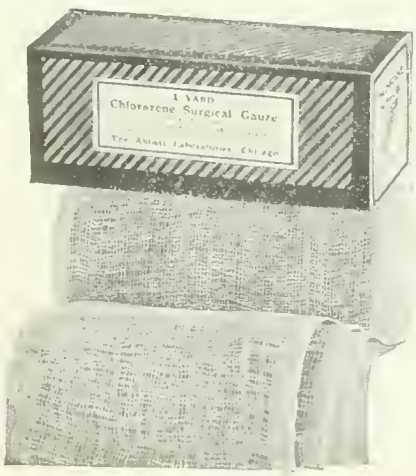
A beautiful "disappearing" cream, prepared according to the formula of Carrel and Daufresne, of Rockefeller Institute; contains 1% of Chlorazene in a neutral sodium stearate base. Powerfully germicidal. Ideal for application to wounds. Very effective in erysipelas, carbuncles, eczema, dandruff, pruritus and other skin diseases. List price: per jar, 80c.

Net price 60c

Chlorazene Surgical Gauze

This gauze contains 5% of Chlorazene. When applied to a discharging wound, cavity or sinus, the antiseptic is given up sufficiently to exert the characteristic germicidal action of Chlorazene.

List prices: 1-yard roll, 55c; 5-yard roll, $2.40;
Net prices: 1-yard roll, 41c;
5-yard roll..... $1.80



Procaine

A Trustworthy Local Anesthetic

Procaine (Abbott) is manufactured by The Abbott Laboratories under license from the Federal Trade Commission and was supplied to the Army and Navy during the war. It is less toxic than cocaine and is probably the safest and best local anesthetic that can be used.

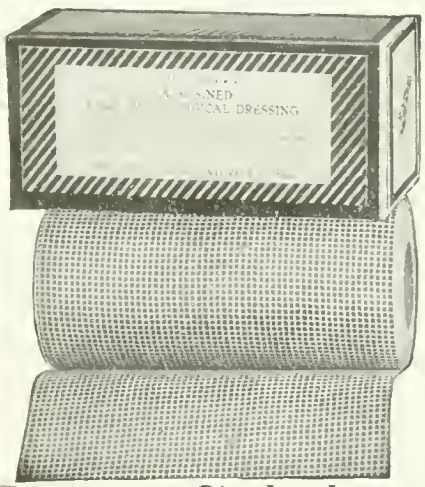
Procaine-Adrenalin Tablets, No. 1.
Bottles of 100. Net..... $1.28

Parresined Lace-Mesh Surgical Dressing

By the use of this Dressing it is possible to apply an antiseptic (Dichloramine-T-Chlorcosane is best), directly to the wound, at the same time providing for drainage, and assuring its removal without pain or discomfort, and with a saving of time and expensive gauze and cotton over-dressings.

List price: 10-yard roll, $3.50;
Net price..... $2.63

Also supplied in boxes of 6 envelopes, each containing a strip 6x18 inches. List price: $1.60;
Net price $1.20



Cinchophen

(Abbott)
(Phenylcinchoninic Acid, U. S. P.)

Indicated in Gout. This is probably the best of all remedies for Gout and the many affections of uric-acid origin. The net price per tube of 20 tablets is..... 94c
Bottles of 100 tablets.....$4.50
Ask your druggist for Abbott's Cinchophen.

Barbital

(Abbott)
(Diethylbarbituric Acid)

This is one of our safest hypnotics and sedatives. One to two 5-grain tablets taken at bedtime will induce quiet, restful, dreamless sleep.

Net price per 100 tablets $3.38

PRESCRIBE BARBITAL (ABBOTT)

Complete Price List of the Abbott products or special literature on any of the items shown above, will be sent on request. Your orders will be filled promptly, direct through our home office or convenient branch points, or through the regular channels of the retail drug trade or physicians' supply houses. Urge your druggist to prescribe for your prescription convenience. Prices are subject to change without notice. Get your order in early.

ANATOMICAL ASSOCIATION IN CHINA

A call recently sent forth for the organization of an Anatomical Association in China offers in its favor the statement that one of the objects of such an association is research which may find in the skeletal remains examples of long sought for intermediate forms that have been lost sight of in the differentiation of mankind which it is believed took place in central Asia. In a recent contribution to the China Medical Journal, Professor E. V. Cowdry emphasizes that racial problems are uppermost in China and that through the study and measurement of Oriental types measurements can be standardized and much can be determined in this way as to the fixity and plasticity of types.

IS NARCOTIC DRUG ADDICTION A DISEASE?

The interest of physician and health officers is centered in the test case of a physician being tried under the Harrison Act for prescribing according to his own best judgment for his patients suffering from addiction disease. The Federal courts will undertake to determine in the case of Dr. E. S. Bishop whether a physician may undertake to control the use of habit producing drugs in a patient by the further administration of such drugs, or whether such procedure is to be regarded as pandering to a class of degenerate criminals. Much profitable definition is likely to ensue, in view of the high standing and authoritative position of Dr. Bishop, who in his own writings has mentioned the difficulties of the practitioner of medicine who in treating such patients is "always in constant uncertainty as to the meaning and possible administrations of the laws."

SCHICK TESTS AND TOXIN ANTITOXIN

The following table gives a summary of Schick test work and toxin-antitoxin administration, recently completed, in an institution for children in New York City, which will be of considerable interest to all physicians.

All children who, as listed above, gave positive Schick tests, have been immunized with three injections of toxin-antitoxin, and the Department's Bureau of Laboratories is testing the virulence of the diptheria bacilli isolated from the throats of the children. The large number who gave positive cultures furnishes evidence of the great importance of such work as is concerned. It will be noticed that the number of cases harboring diphtheria bacilli and also giving a positive Schick test decreases with the age—agreeing with the incidence of clinical diphtheria.

As all cases giving a positive Schick reaction have been immunized with toxin-antitoxin, the home may be considered, at this time, to possess an immune child population.

Simmons Institution Bed Design 1962

Physicians and Hospital Workers

Who Consider the Comfort of their Hospital Patients above everything—are greatly interested in this New Series of Simmons "Private Room" Beds.

Every physician knows that most people sick enough to require hospital care, dread the ordeal as much on account of hospital surroundings as anything else.

The idea of being transferred from their own cozy home into a hospital private room that is naturally bare and strange, causes a restless homesickness that is hard to overcome.

It is only reasonable then, in view of a Physician's interest in his patient's welfare, that the medical profession should be interested in this new series of Institution Beds, one of which is illustrated above.

When the Beds in hospitals (in private rooms especially) are selected with the idea of making patients feel at ease, and "at home," restless homesickness and dread will be greatly minimized. The patient will feel less strange. They will sleep better, and the sleep they get will do them more good.

For the information of Physicians and Directors of Hospitals, it may be said that these new beds are built according to accepted hospital standards in every way. Except for their appearance and superior comfort qualities, and the fact that they are made in a variety of pleasing finishes, their construction is the same as any other of our Institution Bed Designs.

Briefly, they mark an entirely new idea in bed design as applied to hospital requirements. Further information and detailed specifications will be mailed to any Physician, Hospital Director or Superintendent promptly upon request. Address:

Electrically Lighted Surgical Instruments

Twenty years in the manufacture of electrically lighted surgical instruments, if it has not brought perfection in instrument construction, at least has kept the Electro Surgical Instrument Company abreast of the advances made by leading specialists of the medical and surgical profession.

So it is that instruments stamped "E. S. I. Co." speak of the accomplishments of the noted men whose suggestions are embodied in their construction and a service of maintenance possible only in instruments of our manufacture.

Users of instruments stamped "E. S. I. Co." are certain sharers in this service.

Origination begets imitation. Be sure of our exact name.

INDUSTRIAL SURGEONS ASSOCIATE

The organization of an Industrial Surgeons' Association is projected, the Association to affiliate with the Chicago Medical Society. Dr. George D. J. Griffin is temporary chairman, and Dr. Horace C. Lyman temporary secretary of the new organization.

INDIANA GIVES TIME CREDITS FOR WAR SERVICE

An important ruling has just been announced by Dr. M. S. Canfield, treasurer of the Indiana State Board of Medical Registration and Examination. Hereafter, service in the Army, Navy, or Marine Medical Corps may be accepted as time credits for students who wish to take the examination to practice in the state. In adopting the resolution, the Board expressed itself as believing that active service during the war was equivalent to the two years in college, which has hitherto been required of students.

EXAMINATIONS FOR CANAL SERVICE

Open competitive civil service examinations will be held at various places throughout the United States on May 5 and July 7 for physician for Panama Canal Service. The entrance salary is two hundred dollars a month with higher rates for special appointments. Both men and women are eligible. They must be unmarried, must be graduates of accredited medical schools, and must have had at least one year of graduate hospital experience. Application should be made to the Civil Service Commissioner, Washington, D. C., or the secretary of the local United States Civil Service Board.

AN AIR MEDICAL SERVICE

Creation of a special aviation medical service in the army medical corps is expected materially to reduce fatalities among fliers on active service, according to an official announcement.

Statistics compiled by British military authorities are quoted as showing that during the first year of the war 90 per cent of the deaths among British aviators were recorded as physical defects of pilots, 8 per cent to defective planes, and 2 per cent to enemy activity. After the establishment of the air medical service the percenage of deaths due to the faults of the pilots was reduced to 12.

STATISTICAL METHODS AND ACCIDENTS

That statistics are dry and rather useless arrays of figures is disproved by the effect of accident statistics in accident occurrence, says Royal Meeker in the March *Labor Review*.

The analysis by the United States Bureau of Labor Statistics of accidents by length of disability and severity of injury directed the attention of those responsible for the direction of industry to the causes of the more severe accidents and the resulting correction of faulty lay-out equipment and the use of mechanical methods have almost entirely eliminated certain accidents with heavy toll of deaths. Statistics indicate that the education of the workmen reduces very greatly the number of accidents.

Dr. Meeker argues for the adoption in all the United States of uniform accident reporting blanks, these reports to be tabulated according to the rules of the International Association of Industrial Accident Boards and Commissions, to facilitate their speedy and economical analysis and the incorporation of the findings in the objectives of the safety movement.

HAY-FEVER
Can be Prevented

Industrial physicians and health officials will be especially interested this year in Pollen Antigen because through its use absenteeism and lowered production due to Hay-Fever can be prevented.

CLINICAL results covering more than 12,000 cases, attest the value of **Pollen Antigen.**[1] During the past five years, from 1915 to 1919 inclusive, **Pollen Antigen** has afforded relief from hay-fever by conferring an average protection of 82.7%.

THE treatment with **Pollen Antigen** should be started six weeks before the date of the usual onset of hay-fever. Even in those not protected, the symptoms are usually rendered mild and the attack cut short.

POLLEN Antigen is now universally used for hay-fever because:

1. Contains all the antigenic properties of pollen grains.
2. Will not deteriorate.
3. Standardized by complement fixation.
4. May be used without preliminary diagnostic tests.
5. Gives uniformly consistent results each year.

REQUESTS for further information are invited.

14 Cents

is about the cost at this writing of a breakfast of bacon and eggs.

One Cent

is the cost of a big dish of Quaker Oats. Yet the oat is almost a complete food—nearly the ideal food. It is well-balanced, rich in minerals, and it yields 1810 calories per pound.

Saves 90 Per Cent

Quaker Oats costs 5½ cents per 1000 calories. At present writing meats average about 45c, fish about 50c, and eggs about 70c.

So Quaker Oats, for the same calory value, costs about one-tenth the average cost of the foods we cite.

Do you not think that in these days such facts should be made known?

Quaker Oats

Extra-flavory oats which cost no extra price. They are flaked from queen grains only—just the rich, plump, flavory oats. We get but ten pounds from a bushel. Such flakes make the oat dish doubly likable.

The Quaker Oats Company
Chicago

NATONAL CONFERENCE ON IMMIGRATION

For the first time in this country a conference was held in New York April 9, 1920, in which five hundred delegates, representing thirty racial groups, together with national leaders in industry, finance, agriculture, labor and education met to discuss the complex problem of the immigrant. Coleman du Pont, chairman of the Board of the Inter-Racial Council, declared that the expansion of our industries by means of imported labor makes it obligatory to provide for such immigrants a place for their proper development.

Selection of immigrants on a basis of nationality is absurd, said Louis Marshall in analyzing the numerous immigration bills now before Congress. Exclusion of the mentally, morally, and physically unfit he declared sound, but the literacy test should be removed, at least from agricultural laborers and those who desire to engage in domestic service.

Racial antipathies, civic education, naturalization, and other phases of the process of assimilation were discussed. It is just as essential, it was agreed, for America to have immigrants to develop as it is for immigrants to have America. A proper understanding of the interdependence involved must be reached and a proper working basis achieved if the immigrant is to develop and prosper, and if America is to avoid receiving the European discard.

THE NATIONAL TUBERCULOSIS ASSOCIATION

NO better index of the broadened scope of the attack on the tuberculosis problem can be cited than the range of subjects covered and the character of the material presented at the recent meetnig in St. Louis of the National Tuberculosis Association. It is now fairly well appreciated that a properly organized tuberculosis campaign constitutes a community health enterprise in which is overlooked no contributory factor to depletion or reduced resistance, whether nutritional, industrial, inherited, or dependent upon public health conditions. The importance of the last named factor is apparent in the light of the statement by Dr. Victor A. Vaughan, president of the association, that nearly one hundred per cent of our urban population suffer from tuberculous infection. Clearly if "tuberculosis is incident to our civilization," it becomes the task of civilization to eradicate the scourge by thought-out means.

The need of early diagnosis was emphasized with the implied corollary that the concentration of effort must be on the early detection of the disease. The program of this section evaluated certain physical signs, brought out the latest developments in laboratory aids to diagnosis, classifications based on physical signs and the bearing of concurrent conditions. The value of these discussions to workers in the field of tuberculosis detection and prevention is attested by the personnel of the men presenting the various subjects. Experimental studies bearing directly on the problem were various nor was this work divorced from its direct clinical bearing, as several joint discussions provided the proper correlations. The lighting up of latent infections, heightened susceptibility from war strain or subsequent to influenza, the measure of vital capacity, what constitutes rest, remedial occupation, racial factors, each receiving its quota of earnest discussion. Gerald B. Webb, of Colorado Springs, was elected president.

ROYAL BAKING POWDER

ABSOLUTELY–PURE

The Prudent Housewife Uses No Other

Contains No Alum

FOR DIET CONTROL IN INFANT FEEDING

The choice of these dependable products affords the physician convenient means of selecting food mixtures suited to the individual requirements of individual cases.

MEAD'S DEXTRI-MALTOSE NO. 1

(With Sodium Chloride 2%)

For general use in infant feeding. Especially indicated in infants recovering from diarrhoea, infants with feeble powers of digestion who have tendencies to diarrhoea. Valuable as an addition to Protein Milk.

MEAD'S DRY MALT SOUP STOCK

For difficult feeding cases. Indicated in marasmus, weight disturbance (failure to gain), infants afflicted with recurrent diarrhoea from intestinal indigestion, and those cases occasionally met which do not do well on milk, water and sugar mixtures.

MEAD'S DEXTRI-MALTOSE NO. 3

(With Potassium Carbonate 2%)

For use in constipation, when boiled feedings are used, or where the addition of potassium to the infant's diet is indicated.

Full information regarding these products furnished on request.

MEAD JOHNSON & CO. Evansville, Ind.

Thermolite
LIGHT AND HEAT INFUSER

Delivers Radiant Light and Heat in PARALLEL Rays

EXTREMELY EFFECTIVE IN THE TREATMENT OF

Neuralgia	Gastralgia	Rheumatism
Arthritis	Earache	Lumbago
Dermatitis	Laryngitis	Neuritis
Dismenorrhea	Mumps	Ulcers
Shingles	Bronchitis	Cystitis

and many other conditions.

The industrial clinic or hospital equipped with this scientifically designed therapeutic lamp can quickly relieve many conditions which otherwise would cause layoffs of workmen and consequent reduction in industrial production.

The delivery of radiant energy in **parallel** rays affords deep penetration, thus reducing inflammation and promoting healing in a most efficacious manner.

Most therapeutic lamps designed for office or clinical use have a single large reflector with a high powered lamp in the center. This does not permit much adjustment in the intensity or illuminating area in front of the reflector, whereas with the Triplex the light can be projected in a curved or straight line, concentrated or diffused, to any degree, and all without focusing the rays.

Send for prices and free book, "Phototherapy."

ThermoLite is supplied in two forms—the **Triplex** for hospital clinics and office use, and **Simplex** (single lamp with or without stand) for home use.

H. G. McFaddin & Co.
39 Warren St., New York City

REJECTS SCHOOL NURSE BILL

A bill to require municipalities to maintain school nurses has just been rejected in Massachusetts, the opposition leading to its defeat being based on the ground urged by a minister that it would allow "inquisitors" to force their way into homes.

EFFECTVE DECREASE IN CRIME

The United States is spending one-third as much for handling criminals as it is for work in all of its educational institutions, said Dr. V. V. Anderson in a recent address before the Women's City Club of Cincinnati, and from 50 to 60 per cent of these criminals are suffering from nervous or mental afflictions which are responsible for the crime. One-tenth of the amount required to handle the results of crime and dependency devoted to the study of child character and personality as they exist in the public schools would effectively diminish crime. The feeble minded child and the psychopath of today constitute the backbone of future social problems. If dealt with early, half of these cases could be developed into useful citizens.

PUBLIC HEALTH SERVICE BUILDING REQUIREMENTS

The Public Health Service Report based on data from the War Risk Insurance Bureau, to the Committee on Public Buildings of the House of Representatives indicates that the service will be required to take care of 30,000 ex-service men during the ensuing year, these patients classified as follows: General medical and surgical, 7,200; tuberculous, 12,400; and neuropsychiatric, 11,000, a total of 30,000. The hospital needs are imperative. An appropriation is asked of $25,000,000 for construction or purchase of necessary hospital buildings.

PUBLIC HEALTH NURSES IN OHIO

With the organization of the state of Ohio according to the Griswold Health Law almost completed, there are 105 public health nurses now at work in Ohio, not including nurses employed by industrial plants. Using as a basis the census of 1910 for the state, this gives one public health nurse to every 14,320 population. Of the eighty-eight counties of the state, thirty-three have as yet no nursing service, although thirteen have made definite provision for the employment of one and are only waiting until one can be found, leaving but twenty counties without any provision for nursing service.

HOUSING IDEAS FROM ENGLAND

The Government and organized labor have an interesting plan. Under the Housing Act of 1919 the British government accepted responsibility for most of the municipal building enterprises. The workers, organized into a guild, supply and control all the labor, the Government pay the cost of the labor plus 10 per cent. The plan is to be put into effect first at Irlam, in the outskirts of Manchester.

Municipalities have reported building sites numbering 3,165, aggregating 29,435 acres and providing for approximately 294,000 houses. The collective system of dealing with the housing situation as against the competitive principle adhered to in the United States will be watched with interest.

The nutrient value of VIROL illustrated in a number of cases, particulars of which have been supplied by medical men.

CASE No. 6

Baby Coppin was a mere skeleton at one year old. He weighed under nine pounds. It was thought he would not live.

VIROL brought about this remarkable change. Here he is a fine, healthy, well-developed boy, without an ailment. Our records contain the authentic history of a large number of cases showing similar improvements. These have been communicated by the physicians in charge.

In glass jars: 50c, $1.00 and $2.00.

Liberal samples and interesting literature sent to physicians on request.

VIROL is nutritive food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

Children brought up on Virol have firm flesh, strong bones and beautiful color. Palatable in flavor—children love it.

Virol

Used in more than 2000 hospitals, sanatoria, and infant clinics in Great Britain

GRADUATE INSTRUCTION AT TORONTO

Graduates in medicine may now receive the most advanced type of clinical instruction at the University of Toronto. A standing committee has been appointed whose duty it is to give any graduate interested advice as to clinics and lectures which should be taken. This post graduate work will be supplemented by extension lectures arranged by the committee to aid medical societies or groups of physicians who desire to keep up to date.

MEDICAL INSPECTION IN MISSOURI

Missouri has been backward in caring for the health of school children, declares Dr. Herman E. Pearse, chairman of the Public Health and Legislation Committee of the Jackson County Medical Society. For the first time in the history of the Society the county delegation has been instructed to urge legislation, the measure advocated being to provide competent medical inspection in Missouri schools.

CONSERVE HEALTH OF WOMEN

The New York State Industrial Commission has recently issued a bulletin which considers the number of pounds weight a woman in industry may safely be allowed or directed to lift. Specific physical injuries and decreased production were both made the study of statisticians in England in an attempt to arrive at a definite ruling in this respect.

Fixing standards of weights that may be lifted by the woman worker depends upon the nature of the work. To shift a given weight from one bench to another is quite a different thing from carrying the same weight, or from having to lift it as high as the head.

New York leads in the limit of weight to be lifted by women in industry. In France, where hand carts, trucks and wheelbarrows are in common use, definite regulations have been evolved.

It is agreed that the effect of fatigue is shown in irregular attendance and that the effects of over-strain were removed on a change to lighter work.

FATIGUE AND INDUSTRIAL PROFIT

"The industrial worker," says Dr. Frederick S. Lee in the Public Health Reports of January 11, 1918, "from the standpoint of industrial physiology may be looked upon as bringing to the general physical equipment of the factory his own bodily machine, the most intricate of all the machines used in the plant. This machine must be understood, it must be constantly watched, it must be used intelligently, and it must not be abused. Like other industrial machines, it can be worked at different speeds, but unlike other industrial machines it cannot be worked for an indefinite period because it is subject to the limitations of fatigue.

"Fatigue delays work, diminishes output, spoils goods, causes accidents and sickness, keeps workers at home, and in all these ways is an obstacle to efficiency. How fatigue can be kept down to its lowest reasonable limit, how the working power of the individual can be maintained from day to day and from week to week and be made to yield a maximum output without detriment to itself and to others—in other words, how the human machine can be used so as to obtain from it the most profit—constitutes one of the greatest industrial problems of the day."

Kellogg's
KRUMBLED BRAN

An exceptional constipation corrective

An all-bran laxative food that has no resemblance to ordinary bran in appearance and flavor, Kellogg's Krumbled Bran has a delightfully pleasing goodness that appeals to the patient.

You never tasted bran so good—thoroughly cooked and ready to serve. Every package sealed in the Kellogg "waxtite" wrapper which positively insures the original freshness and flavor being retained.

This signature on every package guarantees the genuine— W. K. Kellogg

NEW PENNSYLVANIAN COMMISSION

A Commission has been appointed by Governor Sproul of Pennsylvania to investigate those accidents and sicknesses which are not compensated for by the Workmen's Compensation Act of Pennsylvania.

The members of the Commission appointed by the Governor are:

William Flinn, Pittsburgh; William Draper Lewis, Philadelphia; Dr. Francis D. Patterson, Philadelphia; G. Oram Ring, Philadelphia; William H. Kingsley, Philadelphia.

The members named by the president pro tem. of the senate are:

S. J. Miller, Clearfield; Morris Einstein, Allegheny; Charles W. Sones, Lycoming.

Those named by the speaker of the house are:

William T. Ramsey, Delaware; John J. Flynn, Elk; and Theodore Campbell, Philadelphia.

OFFICE OF MINISTER OF HYGIENE

Prime Minister Clemenceau having resigned, M. Millerand, his successor, was charged with the organization of a new cabinet. According to the *Lancet*, he has introduced an inovation by creating a new ministerial office of social hygiene, social insurance and social provision. The question first came up in 1902, at the time the law in regard to the protection of public health was passed.

It was again agitated when the application of the law was extended so as to include the antituberculosis and social hygiene dispensaries. In 1913, Dr. Vaillant, a Paris deputy, had taken the initiative and demanded the creation of the office of the minister of public health, and M. Mirman, at that time *directeur de l'assistance et de l'hygiène publiques au ministère de l'intérieur*, had favored such action. In 1916, Jules-Louis Breton, deputy of the Department of War, presented a more modest proposal to the Chamber of Deputies. He reported that the office of undersecretary of state for hygiene, in connection with the service of the minister of the interior, be established. The year before, the Government had created the office of undersecretary of state for the Service *de santé militaire;* but during the great epidemic of influenza that raged in France in 1918, it was found that the duties and functions of two duly appointed officials clashed, namely, the undersecretary of state for hygiene, associated with the office of minister of the interior, and the undersecretary of state associated with the Service de santé militaire. In view of this fact, M. Clemenceau organized, under his chairmanship, a ministerial conference, grouping together all the services having to do with health and hygiene, which at that time were scattered through five ministerial departments.

Under Prime Minister Millerand this temporary arrangement has taken a permanent form, and the office of minister of hygiene has been conferred on Jules-Louis Breton, as already stated. Having been chemical engineer, adviser to the chamber of deputies in matters of social hygiene, and author of the bill aiming to suppress the use of white lead in building paint, Breton was the logical choice for the new post.

DR. PAUL G. WOOLLEY GOES TO DETROIT

The National Pathological Laboratories have established a laboratory in Detroit, with Dr. Paul G. Woolley as director. Dr. Woolley has served in the University of Cincinnati as professor of pathology for the past eleven years and was dean of the college for several years.

FLAVORING EXTRACTS

ARISTON FLAVORING EXTRACTS

Test higher in purity and strength than is required by the Pure Food laws. They are made in a fully equipped laboratory by thorough and careful methods.

One Corner of Our Extract Laboratory.

Only the finest quality of vanilla beans is used in making Ariston Vanilla Extract. They are chopped fine, put into barrels, where they remain in maceration for many months, to allow the alcohol to extract the essence, which becomes rich and mellow in character, with a delicate flavor. It is then drawn off and drips through the percolators ready for bottling.

Besides the Vanilla, we make all flavors, including Vanilla-Tonka, Orange, Almond, Lemon, Peppermint, Wintergreen, Clover, Celery, Nutmeg, Sassafras, Anise, Onion, and others.

You can rely on our extracts as being pure and wholesome and the best that can be produced.

HAZARDS IN RUBBER INDUSTRY

The Section on Rubber Industries of the National Safety Council is planning important activities in studying the health and accident hazards of rubber plants. At a recent meeting of the Committee it was decided to publish during the year twenty-six bulletins depicting the principal hazards in the rubber manufacturing industry and methods for their elimination. A tentative program for the 1920 Congress of this section called for three sessions and among the topics to be covered are: The present and future of safety in the rubber industry; health and hazards in the rubber industry; and methods of educating workmen in safety.

SIDE LIGHTS ON MORTALITY

The necessity for an intelligent selection of risks by life insurance companies has required an intimate knowledge of the mortality tables and the various insurance companies have been instrumental in furnishing the most definite and reliable statistics. Some interesting facts are brought out at the recent American Life convention at French Lick, Ind., in a paper read by Robinson G. Hunter. He suggests that the American Table of Mortality exaggerates the death rate at the younger ages. Comparing the mortality among American women with the expected deaths calculated by the American Men Mortality Table, the ratio of actual to expected was 110.8 per cent during the first five years, 91.5 per cent in the subsequent insurance years, and 94.4 per cent for all insurance years. The lower mortality among women than among men is due to the large proportion of single women among the insured.

There is, of course, a definite relationship between the mortality experienced and the plan of insurance. It is suggested that the thrifty and provident men who take limited payment and endowment insurance, because of their more methodical and careful life are subject to a lower mortality than the improvident class.

For the purpose of determining mortality according to habitat, the United States was divided into ten groups of states according to geographical situation and economic conditions. The group that shows the highest mortality was Alabama, Arkansas, Louisiana, and Mississippi. The middle western states show the lowest mortality. The wheat growing districts of Manitoba, Alberta, and Saskatchewan show the lowest mortality in Canada. Climatic factors alone cannot be responsible for the conditions shown in the mortality tables; living conditions, occupations, nationality, all contribute their part.

The death rate from accidents is interesting. Present investigation shows that the death rate from accident increases with the increase in attained age for any given duration of policy but decreases with the duration of policy in spite of the increased age, that there is a lower death rate from accident in the sixth and subsequent years than there is in the first five insurance years.

Almost without exception the mortality on policies of large amounts is unduly high. Reasons assigned are that applicants for large amounts regularly eat and drink more than the average, and are more subject to "The interested intrusion of unsound lives." In these cases it is suggested that more rigid medical examination should be employed to exclude the beginnings of degenerative disease.

If he has no love for the work he is engaged upon it becomes an intolerable burden, and having become a burden, it tends to react upon his character, and makes him slack, inattentive and careless.—Robert W. Mackenna.

MODERN MEDICINE

Volume 2. JUNE, 1920 Number 6

NOTES AND COMMENT

GENERAL HOSPITALS AND TUBERCULOSIS

THE public endorsement by the Surgeon General of the United States Public Health Service of the resolution passed by the National Tuberculosis Association in 1916, recommending that general hospitals should admit tuberculous patients and provide separate wards for this purpose, opens a question that should now be kept before the public, the medical profession, and those who are responsible for hospital administration until it is properly disposed of. It is a question that cannot be satisfactorily settled except by actually carrying out the proposals made by the National Tuberculosis Association. It would be difficult to improve upon Surgeon General Cumming's admirable summary of the advantages to be gained by providing a limited number of beds for the tuberculous in every general hospital. Such provision would "insure earlier diagnosis, would make possible the training of interns, would popularize treatment in the home climate, would provide convenient facilities for the observation and prompt treatment of patients," and would eventually bring about "a sharpened perception and higher degree of skill by which the family doctor would make earlier diagnoses, and even forestall the development of clinical tuberculosis in the adult before a definite diagnosis is possible."

The question naturally arises how can impetus be given to, and recognition won for, this important public health movement. The attention of tuberculosis associations was in an earlier day largely concentrated on the establishment of sanatoriums; in a later stage of the tuberculosis movement the efforts of those interested were directed mainly to the creation of tuberculosis clinics. Experience has demonstrated the weakness of the tuberculosis clinic standing alone, without hospital support. It is not always easy to make a prompt diagnosis of cases which present themselves at the clinic. The opportunity to put patients to bed at once under adequate control is invaluable—indeed, indispensable to the proper functioning of a tuberculosis clinic.

The next great step in the tuberculosis movement should be a sustained effort to provide definite clinical facilities, however limited, in connection with every existing tuberculosis clinic. The tuberculosis clinics of the country should be immediately graded, and only those clinics which control clinical facilities be placed in Class "A" and publicly recognized as clinics possessing complete facilities. This, of course, does not mean that a new, diminutive, and relatively costly tuberculosis hospital should be created for each clinic now in existence. A more rational procedure would be the establishment of a working connection between the clinics and existing hospitals. The contribution of hospitals to the public service would thus be greatly enhanced, the clinics would be strengthened, the public mind would be swept free of harmful misconceptions, and hospital interns, into whose hands the whole public health movement of the future eventually must be committed, would not enter into practice, as they often do today, lacking in the power to make an accurate diagnosis and a reasonably correct prognosis in cases of pulmonary tuberculosis.

STATISTICS OF SICKNESS IN INDUSTRY

NUMEROUS industrial plants are instituting statistical records to obtain information concerning the amount of sickness among employees. This movement is fostered by various associations and by the United States Public Health Service. It is a commendable thing in itself if for no other reason than to call attention to the fact that sickness is a serious factor among workers.

There is danger, however, in the movement that misleading interpretations will be formulated on incomplete statistics. Not many plants have the facilities to check up sickness among the employees so as to make the statistics dependable. Unless there are physicians and nurses to whom the employee reports, or nurses who go out to the homes of those who are reported sick, there is small likelihood that the statistics will be correct. Sickness is quite universally the excuse for absence. Are the statisticians to rely on the unsupported statement of an employee that he was sick when he returns from an absence of two, three, or more days? What about the man who is sick for several weeks, and dies, or who, upon recovery, does not return to his old employment but finds a new job? His sickness does not appear in the statistics. Those who are depending upon the recording of sickness to determine sickness rates will be disappointed. No accurate figures of sickness can be obtained in this way except in those cases where, by insurance arrangements or by liberal employment of physicians and nurses, a complete check is kept on all sickness and its duration.

THE AMERICAN MEDICAL ASSOCIATION AND HEALTH INSURANCE

THE House of Delegates of the American Medical Association passed the following resolution at the New Orleans convention on the subject of health insurance:

RESOLVED, That the American Medical Association declares its opposition to the institution of any plan embodying the system of compulsory contributory insurance against illness, or any other plan of compulsory insurance which provides for medical service to be rendered contributors or their dependents, provided, controlled, or regulated by any state or Federal Government."

This resolution is decidedly a negative way to solve the problems which have been pushed to the front with the agitation for health insurance. It will help very little in constructive leadership on these problems.

The resolution raises many questions. Is it intended to disapprove the idea of health insurance completely? Does the Association believe in compulsory insurance which is not contributory, or in contributory insurance which is not compulsory? Is this resolution to be construed as opposition to compulsory accident insurance, or will the fact that such insurance is non-contributory protect it? Does the Association favor private insurance to public insurance? Does the Association mean to declare against the control or regulation of insurance by the state or Federal governments; or does it object, also to mutual benefits providing medical service? Is this resolution to be construed as an objection to the extension of public medicine, as, for instance, the plan outlined in the New York Health Center Bill.

The Association passed a second resolution which may help to clear up the ambiguity of the first. It declared for an investigation of "the relative adequacy of medical service and relations of the profession to the public." The study contemplated by this resolution will doubtless take into consideration the present status of the physician with respect, not only to medical service under accident and health insurance, but also the many phases of organized public medicine.

THE EIGHT-HOUR DAY AND EFFICIENCY

DISCUSSION has been rife for many years on the question of the relative production by the eight hour day and the ten hour day in industrial plants. Labor leaders, students of labor, and some employers have held that in occupations more or less monotonous the worker will produce as much in eight hours as he will in ten. This subject has recently been under expert analysis by the United States Public Health Service, and their conclusions ought to have weight when backed up by the practical demonstration of scores of industrial plants.

The main conclusion of the study is that "the eight hour day is not only more efficient than the ten hour day in industrial plants, but is more economical." It is found that with the eight hour day there is a steady maintenance of output.

It is believed by the Service that these conclusions are based on so careful a study and on so large a number of employees that they may safely be applied by industrial engineers generally. The report embodying these conclusions will be read with interest by everyone interested in increased production. If American industry is going to produce efficiently and continuously, it will be because the human factor in industry is attended to. If sound psychological principles call for the eight hour day, then it should be adopted, even at the expense of output; but when it promotes sound psychological principles, industrial efficiency, and economical work there should be no hesitation as to the immediate adoption of the eight-hour day.

A DISCUSSION OF MEDICAL PRACTICE RELATING TO HEALTH CONSERVATION

By S. S. GOLDWATER, M.D., Director, Mount Sinai Hospital, New York City

WHAT are the most important services that physicians can render?

Answer.—They are four: the first is to conserve the health of the well; the second, to detect and, when possible, to arrest incipient disease; the third, to restore the sick to health; and the fourth, to ease the sufferings of those who are sick, injured, old, or feeble.

Question.—Is the relative importance of these important functions generally recognized?

Answer.—It is not. In the medical schools the attention of instructors is fixed mainly on diseases having a definite pathology; it is to the diagnosis and treatment of these diseases that most time and thought is given, after indispensable preliminary instruction in the underlying physical and biological sciences. The brief courses that are given in preventive medicine and personal hygiene do not begin to do justice to these subjects, and the whole atmosphere of the school prompts the student to follow in the footsteps of teachers who have won fame and fortune, either as skilled laboratory workers or as clinical specialists.

Question.—You will nevertheless concede that remarkable progress in preventive medicine has been made in this country within the memory of men now living?

Answer.—True; but for this the medical schools can claim only part of the credit. A large part of what has been accomplished has been due to the efforts of sanitary engineers and social workers, untrained in medicine. Moreover, the progress that has been made is not enough. Those who regard the conservation of health as the foremost of human interests are far from content with what has been accomplished in preventive medicine. Certain communicable diseases have been either stamped out or brought well under control; while others, including the virulent and frightful pandemic disease that in 1918 destroyed from eight to ten million lives, continue utterly to baffle science. Then there are such diseases as syphilis, gonorrhea, and malaria—theoretically in the "preventable" class—and diseases susceptible either to arrest or control, such as tuberculosis, cancer, and diabetes, diseases of the heart, blood vessels, and kidneys, diseases of the digestive tract, or of the nervous system, the actual control of which is far from satisfactory, owing to the lack of personal cooperation.

Question.—To what do you attribute the want of cooperation? Are people not properly instructed in regard to the transmission or causation of such diseases?

Answer.—They are not. Physicians, who alone can do this teaching as it should be done, whose potential power to control and direct the conduct of men is greater than that of any other class, of whom it may be said that they hold the key to happiness itself, are themselves not properly taught; they scarcely realize the splendid opportunities that are theirs.

Question.—You appear to have in mind the further accentuation of public health education. If the efforts heretofore made have been unsuccessful, there must be a reason. What is it?

Answer.—Health organizations, both public and private, have attempted to educate large numbers of people by means of tracts and lectures. Latterly, health departments and numerous private organizations have tried by these means to popularize the principles of personal hygiene. However, it is well known that the application of the rules of hygiene must be varied with each individual, and most health officers are now ready to acknowledge that but little further progress is likely to be made except through the better ordering of individual lives by the people themselves. Health departments, unfortunately, cannot through existing machinery sufficiently influence the average man. As for private organizations which are active in the health movement, they are successful in their teaching only in proportion to the volume of their personal work,

The power of physicians to control the conduct of men is greater than that of any other class; it is not fully exercised because medical education is defective. The medical profession itself must study habit, character, and environment and assume leadership.

Sympathy and understanding, which physicians often lack, enable quacks and healers to make great inroads on medical practice, and the widespread influence of the family physician, supported by the health department, the hospital, the diagnostic center, the trained nurse, and the health visitor must be restored. Unless medicine is reformed, America will lead in quackery as well as in scientific medicine.

which is far from being adequate. Meanwhile, the great mass of the medical profession fail entirely to adopt the point of view or the methods of health conservation.

Promote Art of Right Living

Question.—You say that most physicians contribute nothing to health conservation. Are there any typical exceptions?

Answer.—The physician who is doing most to guard the health of his clients is the old-fashioned practitioner who watches over whole families, attending to their minor ailments as conscientiously as to their graver maladies, and accepting the duties of friend and confessor as well as the particular rôle which his professional training and title assign to him. He knows the heredity of his patient, the diseases through which he has passed in infancy and childhood, the consequences of these diseases, his personal habits, his occupation, and home surroundings. He is a psycho-analyst by intuition, if not by training; sympathy and common sense oftentimes serve him in the absence of any systematic knowledge of social science. To the great consultants and specialists, the intimate personal history of their patients, their spiritual and mental lives, are unknown and afford no particular interest; it is for this reason that specialists sometimes prescribe treatment which falls wide of the mark, and even excites ridicule.

Question.—Is this true of all classes of specialists?

Answer.—No; for example, psychoneurologists are beginning to inquire into certain phases of personal experience which play a rôle in the production of nervous and mental symptoms. Through their work and writings, and that of their co-workers, the psychologists, popular interest has lately been aroused in mental hygiene. This interest is a good thing; but what is needed is a deep and widespread interest, not in mental hygiene merely, but in the development of all of man's powers, in hygiene itself, in the long but by no means hopeless fight to gain for each individual the full enjoyment of health.

Question.—You said a moment ago that both private and public health organizations had attempted to teach hygiene by means of lectures and tracts. Have they not also employed health visitors, and do not health visitors inculcate ideas of right living, the importance of which you emphasize so strongly?

Answer.—Yes; public health visitors are doing splendid work. They would do still better if they were equipped with expert knowledge and were trained teachers which, as a rule, they are not. Nevertheless, to some classes of people the public health visitor is able to speak persuasively, even with a semblance of authority; but there are not enough public health visitors to reach all of those who are open to their influence, and there are many groups so constituted mentally or so placed socially that they cannot be reached by public health visitors at all, but who could be reached by physicians if only physicians could be induced to regard every patient as a pupil in need of instruction in the art of right living.

A Working Agreement Necessary

Question.—Cannot the health visitor and the physician combine? As a matter of fact, do not physicians readily cooperate with health visitors?

Answer.—Occasionally they do; more often they do not. When the services of a hospital social worker, whose functions are in large part those of a health visitor, are placed at the disposal of a group of physicians in hospital or dispensary, they are accepted eagerly by a few, grudgingly by others, while by most they are flatly rejected. Read carefully the reports of hospital social workers, and you will be astonished at the Herculean efforts that they have to make in order to establish themselves in the good graces of the doctors. Between the lines of nearly every such report may be read the story of an up hill struggle to interest the medical specialists of hospital and dispensary in facts of heredity, of habit, of character of environment, which play such important rôles in dulling the edge of existence, in lowering vitality, in defeating the attempt to win back life in all its marvelous fullness and richness of emotion, experience, and delight. A dozen years ago Richard Cabot expressed the opinion that it was not worth while for any outsider to establish social work in a hospital unless some physician in that hospital had already become aware of his need of such help. "The doctor must first have felt the difficulty of finishing the work which his diagnostic studies begin, or of carrying into effect his desire to go to the bottom of his cases, to find their cause—physical, chemical, hygienic, financial, domestic, emotional, or whatever it may turn out to be—and to root it out."

Question.—And do you, then, disagree with Dr. Cabot?

Answer.—I am disposed to believe that Dr. Cabot did not go far enough. In the long run, I think, attempts to interest the busy hospital surgeon, who is keyed up to the requirements of great emergencies, or of the learned internist, who is intent upon some obscure phase of pathology, in the "social, financial, and physical background out of which individual cases of disease emerge momentarily, and quite misleadingly, at the hos-

pital," will fail. I do not at all deplore this, for the minds of these men are occupied with other things, and are so occupied to advantage. Here are men who, as a rule, will not and should not be distracted with questions that are entirely foreign to their daily thought, occupation, and experience; questions to which their painfully acquired special skill and knowledge can contribute little or nothing of value. I believe that the time has come for hospital social workers to cease tagging after and trying to capture the interest of the medical specialists, for the chase is long and arduous, and the prize, if it could be won, is not worth the effort.

Question.—Do you mean that you are opposed to the growth of specialism in medicine?

Answer.—Not at all. The greater the number of specialties, the more skillful each specialist in his own sphere. However, the specialist cannot escape the defects of his qualities; the closer his study of pathology and symptomatology, the greater his technical ability as a surgeon or specialized therapeutist, the less his comprehension of heredity, character, and environment. The modern hospital or diagnostic clinic functions beautifully up to a certain point, but it does not function completely in a medicosocial or medicopsychological sense. The "system" has no eye to see or mind to perceive the human being behind the "case" with which its organization and records are chiefly concerned. It does not give adequate personal service.

Has it never struck you as singular that while medicine apparently has been growing more and more efficient, an ever increasing number of sufferers has been getting out of step with the regular medical profession and into step with all manner of quacks? An immense territory which should be controlled by educated physicians is in the possession of "fakers" who often supply what highly trained doctors fail to furnish, namely, that sympathy and understanding which are frequently needed in diagnosis, and which often tend to restore a patient's confidence in himself and his future. See how many different people are attempting to do the physician's job! Among others there are the serious minded and helpful but only half trained social worker, the untrained Christian Scientist, of dubious reputation and influence; and, in addition to these, a hundred varieties of pretenders, whom I shall not dignify by naming them. Medical investigators score victory after victory over our common enemies, the bacteria; hospitals are added to hospitals; ambitious schools of hygiene and public health are established and proclaimed as the centers of new thought and the inspirers of new achievement in medicine; health visitors go into the homes of the poor, teaching as well as they can the important facts of life; but the medical profession steadily loses ground. How can physicians take pride in their profession, while children remain poorly nourished, adolescents acquire vicious habits, young women become neurotic, and young men grow old before their time?

New Life in Old Service

Question.—And what remedy have you to suggest?

Answer.—Nothing less than the rearrangement of medical practice itself. Public health administrators must cease to depend on the tract or even on the health visitor to do the doctor's job. The hospital social worker must abandon her efforts to make the hospital organization do what it is not by its nature fitted to do. We cannot by mere legislation suppress the humbugs who worm their way into the confidence of the ignorant; they will continue to succeed until somebody better and more capable offers the help that is needed. The hope of universal health conservation cannot be realized without a new kind of medical service—an old order of service really, but an old order renovated and enriched by the application of new knowledge. Before medicine can function efficiently and completely it will be necessary to restore to life and to widespread influence the family physician, modernized and powerfully supported by precious instrumentalities which were not at the command of the family physician of an earlier generation.

Question.—What are the instrumentalities that you have in mind?

Answer.—They are: (1) A progressive department of health and welfare to fight off the big dangers that can only be dealt with through the exercise of public power—such dangers as the polluted water supply, epidemic diseases, the filth of the city, and the greater but less conspicuous filth of the country; and all the dangers to life and limb that lurk in modern industrial society. (2) Centers for the study and diagnosis of obscure diseases, commanding the best specialized clinical and laboratory aid. (3) Hospitals for the acutely sick, equipped to carry out diagnostic, therapeutic, and nursing procedures which cannot be conducted as well elsewhere. (4) Nurses qualified to attend the sick in their homes. (5) Health visitors for the well and the near well, who are ever pursued by sickness which is always ready to strike the unwary.

Question.—What sort of training do you propose to give to the family physician? Is he to study medicine as it is now taught in our best medical schools?

Answer.—The physician who undertakes the kind of practice that I have in mind will require, in addition to the teaching current in the medical schools, an ampler knowledge of hygiene, an understanding of eugenics, a thorough knowledge of the psychology of character and habit, and a command of those phases of social science which have a bearing on the health of individuals. Above all, he will need to be inspired by an instinctive love of man. "Intelligence and instinct are turned in opposite directions; the former toward inert matter, the latter toward life. Instinct is sympathy. It is to the very inwardness of life that instinct leads us."

Question.—In what manner will the "family" physician of the future practice?

Answer.—He may practise individually and be effective, provided he is ready to call to his assistance, when he needs them, the agencies which I have just enumerated. The rich will profit by his sympathy, skill, and strategy no less than the poor. Much of his best work will be done, I think, in the district "health center" of the future, which the hospital and diagnostic clinic will serve as important laboratory aids. His principal object will be the conservation of health; his method, the method of personal service. He will look and call upon the members of the hospital staff as a high order of technicians, just as the internist and the surgeon now utilize and prize the services of the skilled bacteriologist, pathologist, chemist, and radiologist.

Train Three Medical Groups

Question.—But in order that all this may be brought about medical education will have to be completely recast?

Answer.—Yes; for the future order which is here outlined three groups of medical men will have to be trained: (1) The consulting or hospital group, including the present laboratory workers, experts in the detection and classification of morbid processes—doctors of disease, the basis of whose art is pathology; (2) The public health doctor to whom belongs the prevention and control of epidemics, the practice of sanitation and public hygiene, and the important task of public health education; and (3) The health doctor or body physician, whose aim will be the conservation of the health of the individual and who must have an ample knowledge of medicine, the skill to seek out and the strength and cunning to control all the forces that impinge on the life of the individual, threatening him with injury to body, soul, or mind.

Question.—And when all this has been accomplished, what will become of "hospital social service?"

Answer.—There will be no "hospital" social service; the hospital will confine its efforts to the cure of the sick, the study of disease in its more pronounced manifestations, the teaching of clinical and laboratory medicine, and the training of nurses. Lectures and tracts alone will not usher in an era of health conservation. The rules of hygiene vary in their application, and personal instruction is indispensable. The medical profession itself must assume leadership. Medicosocial work will fall naturally into the hands of the group of physicians whose place in the new order I have tried to make clear. The headquarters for the organized efforts of this group will be the district health center to which health visitors will be attached as skirmishers, investigators, propagandists, and aids.

Question.—How soon will the changes in medical practice that you predict take place?

Answer.—The first contingent of the new order has already arrived; its members are establishing themselves in various parts of the country as the medical officers of health centers, health clinics, and industrial groups.

Question.—And are these men fully qualified to conserve health by all possible means?

Answer.—Unfortunately they are not; but what the newcomers lack in special training, they make up to some extent in intelligence, energy, and enthusiasm. This first regiment is a regiment of volunteers, of the finest moral quality, but self-trained, and compelled to advance into unknown territory, laboriously feeling its way. The future army will consist of trained regulars whose important tasks in human conservation will be mapped out for them in advance and whose education, skilled leadership, and perfect organization will insure their success.

Question.—I am disposed to accept your prophesy, but what will happen if we should both be mistaken and the changes which you foretell do not materialize?

Answer.—In that case medicine will go forward in knowledge, but backward in usefulness. It will develop intensively as science, but not extensively as practice. We shall witness the further refinement of diagnosis and of specialized treatment, the intrenchment of scientific medicine in citadels of research and learning, but the great mass of the people will gather outside of the walls, the easy prey of charlatans. The leadership of the world, which is the goal of American ambition, will be achieved; strangely and unexpectedly, however, it will be a dual leadership—a leadership in scientific medicine, and in quackery. Is it conceivable that the practical genius of America will tolerate such a paradox?

SOCIAL SERVICE AMONG CHILDREN

By A. LEVINSON, Chicago

PRACTICALLY every social worker comes in contact with problems that concern children. Not every worker, however, realizes the importance of this particular branch of social service and the special problems connected with it. The child is a social problem from the day of its creation to the day it enters adolescence, at which stage it becomes a member of the adult family, when it presents again problems of a social nature, although different from those of its childhood days.

WHAT DOES CIVILIZATION DO TO THE CHILD?

The child is to be considered as a mere potentiality. What it becomes is governed by its natural bent, plus the multiple influences of its environment.

The child is dependent upon society for its food, for its health, for its definitions, and is in no way responsible for conditions that make or mar its development.

Given a normal mental equipment and a satisfactory physiological background, free play and careful guidance will bring out all the latent possibilities of the child. On the full discharge of our duty in child nurture depend the hopes of the future.

Before it is born the child is a eugenic problem. The problem then consists of how to help the mother during the creation of the child, how to prepare the world for the appearance of the child, and how to prepare the child for the world. Undoubtedly many children would be better off if they were not born, and the world would be better off without them. It is not however, for us to judge. All we can do is to make the world more pleasant for the future child and make the child more useful to the world.

During its infancy the child presents problems closely connected with its social status. A baby needs food, care, and love. Nature usually provides food for the baby during the first few months of its existence in the form of breast milk. Some mothers, however, are either unable or unwilling to utilize Nature's gift. There is the rich mother who does not care to nurse her child because it interferes with her social duties and there is the poor mother who cannot nurse her baby because she has to go to work in order to supply the necessities of the child.

Care is very essential to the child. Not every mother, however, is able to care for her baby. Nature does not select the fittest as mothers, nor the strongest as fathers. There is the very rich mother who does not want to bother with the child, when she can get her maid to "care" for it. There is the poor mother who by force of circumstances has to leave her child with a neighbor in order to help carry the burden of the family. There is also the mother who is financially able and mentally willing to take care of her child, but does not know how. There is the mother who is willing to get information but does not know where to get it, and there is the mother who is prevented from getting information by well meaning but badly instructed neighbors.

The problem of what to do with the infant who is nursed by a hysterical or maniacal mother, is not easily solved. Occasionally one feels that under no consideration should the child be deprived of breast milk, as long as the mother has a sufficient supply of it. On the other hand, it wears the mother out, and at times one wonders if it is at all safe to entrust a hysterical mother, who often becomes maniacal, with the nursing of her baby. In a large pediatric practice one often comes across a mother who sits home all day, brooding over the health of her child, pulling it from all sides, waking up the child when it is asleep for fear it might faint; trying to put the child to sleep when it is awake; putting a nipple into its mouth every few minutes; and, on top of it all, nursing it at very frequent intervals. In such a case the question to be decided is whether it is best for the mother and for the baby to continue with the breast feeding régime or whether it would not be to the interest of the child and the mother to put the baby on artificial feeding. In such a case the problem becomes still more complicated in relation to the general interest of the child, and the question arises as to whether it is not advisable to remove the child from the mother altogether.

The Traditional Background

Race and nationality are great factors in doing social service work among children. The colored mother cannot be expected to learn the habits of the white mother. The Polish mother cannot adopt American habits in one day or one month. Racial habits are too deeply embedded in the woman and one should not try to get her away

from them. As a rule, they are not harmful; usually they are useful when modified to fit conditions in this country.

Many children become a distinct social problem because of sickness or death of one or both of its parents. It is not a question of finding a boarding place for the child, but of finding a home for it. A home for a child is no easy matter to provide. A mother builds a home by the sweat of her brow. A mother is able to make a home from a mere tent. A home without a mother, however, is an anomaly and is hard to find. Not every institution becomes a home, and not every woman who loves to play with children can take the place of a mother. Children who have been so unfortunate as to be robbed of mother's care, either through sickness or death, present one of the most acute problems of modern sociology. It is strange that in this era of the child, of infant welfare, of child study, so little attention has been paid to the question as to what to do with children who have no mother's care.

A hospital for children is another social problem. In practically every city in this country we have now one or more hospitals for children. The question, however, arises as to whether it is best to place a child in a hospital or to keep it in the home—is a sick child better off at home with the mother's attention or should he be sent to a hospital where nurses could take care of him?

Contact and Contagion

The question of contagious diseases is a burning one. Quarantine is a hardship on the parents, on the neighbors, and on the milk man. On the other hand, a child may be sent to a hospital for contagious diseases with one disease and there contract another, and it so happens that a child coming into a contagious hospital with measles will get scarlet fever, mumps, chicken-pox, and, in case of a girl, even vaginitis. The physician, nurse, or social worker has to gauge the distance, has to weigh and measure the situation, and has to decide in each particular instance whether home treatment or hospital treatment is indicated.

Persuading a mother to send the child to a hospital is often no easy matter. Many mothers, especially those of foreign birth, are afraid of a hospital. Tact needs to be used in explaining to the mother, as at all times one must take the mother's feelings in the matter into consideration.

The sick child's attitude is a problem that should concern social workers. Bringing toys to a sick child is not all that is necessary. The child requires sympathy during illness, and yet must not be spoiled. He must see that interest is taken in his welfare, yet must not be permitted to feel the worries that befall those nearest him. These problems require a knowledge of child psychology.

The convalescent child is an important subject. The convalescent child requires rest of body and mind, graduated exercise and play. It is up to the social worker to study the social conditions of the family before a child is sent home from a hospital, or the future life of the child may be jeopardized.

Social service among tuberculous children, especially those who manifest no active symptoms, is a subject that should be studied with great interest by those who are interested in the social phases of medical problems. The social worker can do more to prevent tuberculosis in families where there is one or more open cases than the physician or the nurse.

Children affected with syphilis, whether congenital or acquired, are a social problem. Unless actively treated sooner or later they develop symptoms of the disease. As a rule, however, the disease is not recognized early and, when recognized the children are either blind or deaf, or present symptoms of juvenile paresis.

The epileptic child, whether the epilepsy is due to syphilis, to trauma, or to an unknown cause, is a social problem. We have not enough epileptic colonies in this country and those in existence are not always of the very highest order. The social worker is often called upon to decide which case belongs in an institution and which one can or should stay home.

Problem of the Sub-Normal

The mentally defective child is very commonly encountered. The question is how to recognize a mentally defective child and, when recognized, what to do with it. A few standard questions should not put a child into the bright or defective class. One child may be mechanically inclined and thus able to arrange a series of blocks. Another child, as bright or brighter than the first, may not be able to arrange the blocks because of lack of mechanical ability. A standard devised for French children may not be adapted to American children, even though the questions have been translated into English. A child's mentality must be the subject of thorough study. The child must be observed for a long period before it is classed as mentally defective. The question of what to do with children who are mentally defective is one that carries with it a great responsibility. Not every mental defect belongs in an institution, where mentality may suffer still more. On the other hand, many sub-normal children who roam the streets would be much better off in an institution than at home. The proper care of such

cases would result in fewer criminals and fewer crimes. The incurable child requires love and interest on the part of the world, and the social worker may become the connecting link between the patient and the world.

The child presents a social problem during adolescence, the stage when the child suddenly feels a stream of life in him, when he is trying to find an outlet for his energy. The worker who deals with adolescent children must know the physiology and pathology of adolescence and must allow for it accordingly.

The child's nervous system is extremely unstable. The child's habits are not fixed. The good child may not always remain good, and the bad child may still change his ways.

In addition to a knowledge of child psychology, one who does the social service work among children should know a great deal about child physiology. Even a knowledge of the child does not suffice. No child can be separated from his parents. If one wants to study a particular child he must take into consideration the mother of the child, the father of the child, the grandparents, and even the neighbors. While the child is an individual being, it reacts the surroundings by imitation—a characteristic inherent in all children.

Finally, one who desires to do social work among children must love children. No efficient work can be done in any line without love for the work. This, however, is doubly true of social service work among children.

TESTING DRUGS SAFEGUARDS LIVES

The appropriation of more than $4,000,000 made recently for fighting venereal diseases has given the campaign a great impetus. A great part of this amount will be used for publicity purposes, as one of the most necessary factors in gaining control of these plagues is the dissemination of information on the subject.

Already publicity is resulting in thousands of people afflicted doing the rational thing—learning all they can about such diseases, and seeking help from clinics.

In addition to publicity, the United States Public Health Service is taking every precaution to safeguard the lives of the people who apply for treatment by making the most rigid tests of the drugs used in effecting a cure. Before a manufacturer of salvarsan or arsephenamine is permitted to put his product on the market, experts of the Public Health Service inject specimens into white rats to make sure that it is safe to administer to human beings. An hour before the test is made, the water used in dissolving the drugs is freshly distilled, and everything humanly possible is done to insure that the drugs will properly subserve the uses to which they are to be put.

RESPIRATORY TRACT INFECTIONS

WINTERNITZ, Smith and Robinson[1] discuss an unrecognized pathway for bacterial invasion of the respiratory tract. "When a preliminary injury has destroyed the efficiency of the protective mechanism in the upper respiratory tract, it is easy to locate the portal of entry and to follow the course of microörganisms associated with pneumonia. But we know that inflammation of the lung can occur when no gross lesion of the upper respiratory tract exists. In the latter condition, how do bacteria reach the lung? This is the question we have sought to answer. The results of our experience, briefly stated, indicate that in such cases the rich plexus of lymphatics within the submucosa of the trachea supplies the requisite pathway."

By very careful technical procedures these authors studied the lymphatics of the submucosa of the trachea and bronchi and review some of the experimental work on the production of pneumonia on the basis of their discoveries. They conclude that the submucosa of the trachea contains a rich plexus of lymphatics prominent everywhere and devoid of valves. This plexus forms anastomoses with other plexuses in the bronchi and the phenomenon occurs throughout the region of the cartilage bearing bronchi. Drainage occurs to the lymph glands of the peribronchial lymphatics, but continuity of the lymphatic system in the tracheal and bronchial submucosae is demonstrable. The work of Blake and Cecil, producing pneumonia by introducing pneumococci into the lumen of the trachea by needle puncture through the skin, causes pneumonia, according to these authors, by way of the lymphatics to the lung. But, though this lymphatic system provides a pathway for infection, it also serves as a protective mechanism by diverting to the protecting regional lymph glands.

Bloomfield[2] continues his study on the fate of influenza bacilli introduced into the upper air passages. Normal human beings were experimented on, material from an active influenza culture being deposited on the tongue, nasal septum, nasopharynx, or tonsil crypt. Cultures were made at various intervals from the inoculated site. The site of inoculation was also watched for signs of reaction. The result substantiated the work of previous investigators and showed: (1) Influenza bacilli disappeared from the upper air passages within one or two days and in no case was a carrier state produced. (2) No local or general pathological process resulted. (3) In five cases the influenza bacilli isolated later than twenty-

four hours after inoculation were shown to be different strains from those introduced. (4) Influenza bacilli were no longer viable after twenty-four hours suspension at 37 C. The two remaining principles in the summary of his work, it seems to us, are of striking importance. (5) The rapid disappearance of influenza from upper air passages is probably due to a combination of an unfavorable environment with the mechanical flushing processes at work in these regions. (6) The question of the persistence of influenza bacilli in normal throats cannot be finally settled until we possess accurate methods of differentiating various strains of hemophilic bacteria. It would be interesting to see these experiments repeated with view to the pathway of infection described by Winternitz. EDITOR.

MAJOR AND MINOR ROENTGENOLOGY

THERE is just as much reason to distinguish between major and minor roentgenology as between major and minor surgery. Many features of Roentgen practice may be considered as major efforts demanding knowledge of x-ray principles and experience in x-ray practice. Such roentgenologic work as pneumoperitoneum—injection of air in the peritoneum,—ventriculography—injection of air or gas in the ventricles of the brain,—utero-aerography—injection of air or oxygen through the uterus,—pyelography, pyeloscopy, and cystography are essentially major operations.

Gastro-intestinal and plain genito-urinary radiography and accessory sinus and skull radiography are borderline functions which may be done quite ordinarily even by technicians but which assume major proportions if done in a manner equally satisfactory to internist, surgeon, and roentgenologist. Stereo-chest technic is not major, but chest interpretation is.

All bone and tooth work is minor roentgenology.

Deep therapy of malignancy is essentially major work, requiring special preparation in study, the experience of clinical application, and the courage of optimistic practice.

No matter how complete the x-ray installation, the results in x-ray exposures, interpretation, and therapy can never be obtained unless a well trained roentgenologist is in charge.

Technicians can produce plates and grind out therapy, but the values to the patient are measured by the supervision of an experienced roentgenologist.

The profession will eventually be forced to recognize the demands of the given case for major or minor Roentgen assistance in diagnosis and therapy. E. H. S.

LOCALIZATION OF BRAIN TUMOR

MANY things combine to promote real progress in the art of healing. The integral parts contributing to such progress are rarely discovered simultaneously, but in a sequence covering many years or even centuries, and before we can mark a milestone in our advance, we need to overcome several fundamental difficulties. Normal anatomy must be known; then the pathological anatomy, the etiology, the realization that the pathological anatomy exists; the means of diagnosing the condition; and the treatment. In some instances it is the treatment which still must be developed; in others, the treatment is further developed than our powers of diagnosis. In the latter category we can list brain tumor. The surgical treatment of brain tumor has been put on a fairly firm footing, provided the patient comes to operation early enough; but except in a few certain types exact diagnosis is still far from being achieved. True, the etiology is absolutely unknown in the great majority of instances, but in the intelligent use of the known therapeutic procedures is especially restricted by the fact that we have limited means of determining where our operative attack should be directed. Dandy, by his work on pneumo-ventriculography, has gone far in helping us in this direction.

To quote from Dandy's[1] recent article—"Tumors situated in the speech area, in the cortex in the region of the motor centers, or in the brain, in the region of the pituitary body, can be fairly accurately localized by means of the resulting signs and symptoms. However a large percentage of tumors—more than half—are situated in the "silent areas" of the brain and give rise to a series of symptoms at times indicating clearly enough a brain tumor, but that is all—a tumor somewhere in the brain. It is this kind of growth against which our knowledge of treatment is of little avail." In his article Dandy describes five cases, each representing entirely different findings and showing the range of usefulness of ventriculography when tumors of the cerebral hemispheres are suspected. In these cases ventriculography was the sole method by which localization was made.

To inject air into the ventricles an opening into the skull must be made, preferably under local anesethesia. A ventricular puncture is then performed and, after a sufficient quantity of cerebrospinal fluid is drained off, air is injected. The conformation of the ventricles will allow a picture of each ventricle to be taken separately. After the first picture is made the patient's head is carefully turned in such a way that the air will pass

1. Dandy: Ventriculography, Surg., Gynec. & Obst., 1920, xxx, No. 4.

out of the ventricle through the interventricular formina, through the third ventricle and over into the opposite lateral ventricle. Then, with the occiput on the plate, the anterior horns can be photographed and by placing the forehead on the plate the posterior and descending horns will be brought out.

In a general way a very small ventricle is presumptive, though, of course, not absolute evidence of a cerebral, as against a cerebeller tumor or a tumor of the brain stem; when there is a difference in the size of the two lateral ventricles, the tumor is usually on the side of the smallest ventricle. Although an operation in itself, ventricular puncture is a small procedure as compared with exploratory craniotomy or a decompression, and the results obtained in localization of the growth not infrequently make the puncture far more than an exploratory craniotomy.

Dandy concludes with the statement that "with experience and care in the use of ventriculography, I believe few tumors will escape accurate localization."

Dandy has given us a new weapon to use in our fight, a weapon which we believe will be extremely valuable if very carefully and judiciously used but, like all sharp edged tools, the method is no plaything.

A BENZIDIN-POLYCHROME STAIN FOR BLOOD

THIS new blood stain devised by McJunkin[1] has an interest and importance outside of its relationship to his ideas of the nature and origin of the so-called transitional cells of the blood. He claims, and observations with his kind permission of his preparations verify these claims, that the stain not only demonstrates the oxidase granules in the various types of leukocytes which contain these granules, but also shows the cells as they are seen when stained with the usual Wright stain. This is extremely important, as it enables one accustomed to any of the polychrome methylene blue stains to identify easily the various types of leukocytes containing oxidase granules. The study of pathologic blood is made much easier and more certain by this method. Cells of the oxidase series are readily differentiated from the lymphocytic series. Also, the transitional cell, or endothelial leukocyte as McJunkin believes it to be, can be easily identified. This stain should be of much service in the examination of blood preparations, especially since it is easily prepared and used.

STUDIES IN EXPERIMENTAL DIABETES

DOGS were rendered diabetic by removal of the pancreas and then injected intravenously with unfiltered water extracts of fresh pancreas diluted with 0.9 per cent sodium chlorid solution. The preparation was administered slowly and Kleiner[1] found that it usually resulted in a marked decrease in the blood sugar.

This decrease was not caused by dilution of the blood with the fluid injected, since the hemoglobin of the blood did not change. It was not due to increased elimination of sugar because there was a tendency for the sugar to decrease in the urine. This urinary decrease in sugar is believed to be partly due to a temporary toxic effect on the kidney of the material injected.

This investigation is of importance in throwing light on the possible relationship between the pancreas and diabetes. Evidence of an indirect nature has been accumulating ever since the work of Opie that the internal secretion of the pancreas is the main control of carbohydrate metabolism. This work of Kleiner is of great importance as it is the first carefully controlled series of experiments testing the effect of an extract of pancreatic tissue on both blood sugar and urinary sugar.

The various hypotheses concerning the etiology of diabetes are discussed by Kleiner, and the relationship of this recent investigation of his to each hypothesis is considered. Regardless of what other hypothesis is accepted, the diminution in blood sugar by the intravenous injection of emulsion of pancreas undoubtedly adds another link in the chain of evidence in favor of the internal secretion of the pancreas being the main control in carbohydrate metabolism.

The toxic nature of any preparation of pancreas and the inability to utilize these preparations except by administering them intravenously forbids their use therapeutically at present. Kleiner especially warns that this should not yet be attempted.

The importance of Kleiner's work cannot be over-estimated and it is hoped that it will stimulate further work along this line. It would seem as if the utilization of glucose in the metabolism is through the mechanism of an oxidase. Oxidases are widely distributed in nature. Further investigation might discover an oxidase which can be administered first to animals with experimental diabetes and perhaps finally to individuals with diabetes, which might return to normal their perverted carbohydrate metabolism.

THE WASSERMANN TEST—A CRITICAL REVIEW

By WILLIAM THALHIMER, M.D., Columbia Hospital, Milwaukee, Wis.

KOLMER[1] recently has brought out the point that the technic or method should be designated the Wassermann test, and only the results of this test should be called the Wassermann reaction.

In this review of the Wassermann test there will be given in as untechnical terms as possible an outline of the fundamental principles upon which this test is based, a critical analysis of the changes and development in technic since the original method of Wassermann was published, and the significance of the results obtained by these different technics.

The Value of the Test

One not infrequently hears criticism of the Wassermann test. Most especially it is said that it is an uncertain or irregular laboratory test, and that different laboratories not infrequently disagree in their reports on the same serum. This is true to a certain limited extent. To what degree this is limited will be noted directly. The value of the Wassermann test is, however, best summed up by Vedder: "One is impressed by the fact that the Wassermann reaction must be a test of most surprising merit to have survived all the clumsy technic that has been perpetrated in its name."

The limit of legitimate variation in reports from different laboratories on the same serum is as follows: No matter what modification of the original technic is used, provided the actual technical work is carefully and properly done, there should never be a disagreement about a four plus reaction. With some technics undoubtedly some false positive results occur, but this means that some non-syphilitic sera are reported one or two plus, never stronger. Also, sometimes one, two, or even three plus reactions will be differently reported. Reactions of these strengths are mainly of value in following the treatment of already proved cases of syphilis, so that, whereas this divergence is unfortunate, it can readily be understood when we come to consider the various modifications in technic. Even so, this is not an insuperable difficulty, as the value of the test in controlling the treatment of a case can be fully utilized by the simple expedient of having all the tests done at a single laboratory, making sure that it is a reliable laboratory, in which case all the results will have the same relative significance. It can be stated, in all probability with no fear of contradiction, that if on the same serum one laboratory reports a four plus reaction and another reports a negative, then one laboratory or the other, or both, are doing unreliable work.

We believe that every physician should understand the principles on which the Wassermann test is based, in order that he can properly understand what the Wassermann reactions from the laboratory mean, and how they should be interpreted and applied. Although scarcely two laboratories perform this test exactly alike, if the fundamentals are appreciated on which all of these tests are based, then it is simple enough to evaluate any given test or technic. Also, proper correlation of the results of the tests with the clinical aspect of even a few cases will readily inform the doctor whether the laboratory performing the tests is to be relied on or not. Therefore, at the risk of using valuable space for elementary information, the principles underlying Wassermann test follow:

Principles of the Test

Any material is an *antigen* which, when injected into an animal, causes substances to be formed which react with or against the injected material. These substances which are formed by the animal are *antibodies* and are usually found in the circulating blood, that is, the plasma or serum. Some of these are *immune antibodies*, such as *antitoxin;* some apparently have no immunizing or protective action; at least, we have not yet discovered the protective properties of some of these antibodies. Most antibodies show a marked specificity, that is, they react only with or against an antigen which has excited their production, or react stronger with their specific antigen than with other antigens, even though these antigens be closely allied. Thus, typhoid agglutinating antibodies may slightly agglutinate the closely related paratyphoid organisms, but never do this as markedly as they agglutinate typhoid bacilli.

Some antibodies act directly on the antigen; others act only in the presence of a substance called complement, which is present in varying amounts in the blood of practically all species of animals. Examples of the direct acting antibodies are agglutinins and antitoxins. Examples of antibodies which act only in presence of complement are bactericidal antibodies (which kill bacteria) and the antibodies which give the

1. Kolmer: Am. Jour. of Syph., 1919 and 1920.

specific reaction in the Wassermann test. Experiments seem to show that antibodies which act only in the presence of complement act by attaching, or fixing, the complement to the antigen.

Complement is thermolabile, that is, it is destroyed by heating to 56° C. for half an hour. It also deteriorates in a few hours at ordinary room temperature. Complement fixing antibodies are thermostabile, that is, they resist 56° C. for half an hour.

From this it is easy to see that if syphilitic antigen is brought together with syphilitic antibodies and with complement, then the syphilitic antibodies will attach, or fix, the complement to the syphilitic antigen. That is to say, if a patient's serum fixed complement to syphilitic antigen, then the serum contains syphilitic antibodies. This means that these syphilitic antibodies have developed in the patient's blood in response to syphilitic antigen—*spirochete pallida*, the cause of syphilis—and therefore the patient has, or has had, syphilis. This reaction is called complement fixation, and the Wassermann test, which utilizes this reaction, is a complement fixation test.

Complement Fixation Determined

We must now show how we are able to determine whether complement fixation occurs. This is done by bringing together syphilitic antigen, patient's serum, and complement under conditions favorable for complement fixation. This mixture is then tested for free complement. If the complement is not fixed to the syphilitic antigen, then it is free and can be attached by appropriate antibodies to still another antigen. If antibodies to sheep red blood cells are brought together with sheep red blood cells and with complement at 37° C. a solution of the red blood cells occurs. This is called hemolysis, and can readily be detected in a test tube. Therefore, if to the original mixture of syphilitic antigen, patient's serum, and complement we add sheep red blood cells and hemolytic antibodies for these cells, then, if no hemolysis occurs, all the complement has been fixed originally, which indicates that the patient's serum contains syphilitic antibodies, and that the patient has or has had syphilis. This is a positive Wassermann reaction. If, however, the sheep cells are hemolyzed, then the complement was not fixed in the original mixture, no syphilitic antibodies were present; patient is not a syphilitic, and the Wassermann is negative.

This reaction is sharp and clear cut. Furthermore, the different reagents act according to their quantitative relations to one another. A given amount of hemolytic antibody will dissolve only a given amount of red blood cells in the presence of a certain amount of complement. The fixation of complement by syphilitic antibody is also a quantitative reaction. But the most important fact to realize is that complement fixation by any one combination is not a final, complete, and unbreakable union. If a second antigen-antibody combination is added, such as red cells and hemolytic antibody, with a large amount of hemolytic antibody present, its action may be so strong as to take some fixed complement, and join it to the red cells and convert a positive reaction into a negative one. Because of these facts, it is absolutely necessary that definite suitable amounts of all reagents be used.

Since the Wassermann test is a quantitative reaction, it is necessary to discuss the quantities of the various ingredients used. In the original test described by Wassermann the total volume after everything was added was 5 cc. Most Wassermanns are now done in one-half amounts, the total volume being 2.5 cc. In some laboratories one-tenth amounts are used so as to save materials when large numbers of tests are done. The test with one-half amounts seems the most satisfactory. Ottenberg has suggested that for sake of uniformity and simplicity in reporting Wassermann technic, that all figures be given to correspond to the original 5 cc. Wassermann. Many investigators have done this, and this will be done in the present discussion.

Quantitative Relations

The most important material to be determined and used quantitatively is complement. If an excess of complement is used, more than can be fixed under the conditions of the test, some will remain free, give hemolysis, and therefore false negative reactions. If too little complement is used, the opposite will occur and false positive results will be obtained.

There are different methods to determine the amount of complement to use, the one generally used at present seems undoubtedly the best and the most logical. The best source of complement is guinea pig serum. The complement of this serum is greater in amount and more active against sheep red blood cells than that of any of the other laboratory animals; but the amount and activity of complement varies in individual guinea pigs, so it is universally agreed that it is best to use the pooled serum from a number of guinea pigs. The guinea pig blood is allowed to clot, then centrifuged and the serum pipetted off, care being taken not to carry over any red blood cells. This is usually diluted with nine parts of normal saline solution, making a one to ten solution. It is important to use chemically pure so-

dium chlorid for making all the salt solution used in the Wassermann, as otherwise impurities in the salt will cause unusual things to occur to the sheep red cells, such as agglutination, or abnormal resistance to hemolysis.

The complement is standardized by determining the minimum amount which, with a sufficient amount of sheep red cell hemolytic antibody—usually spoken of as sheep red blood cell amboceptor—will hemolyze the amount of sheep cells used in the test. This is called the unit of complement, or complement unit. One cc. of a 5 per cent cell suspension in normal saline is the amount used in the original Wassermann. The sheep blood is collected in sodium citrate solution or defibrinated, washed five times in normal saline, and then packed by a high power centrifuge run for a given length of time, such as seven minutes. This gives a fairly uniform concentration of the red blood cells.

There are a number of ways of doing these standardization, or preliminary, tests. Regardless of the method used, everyone is agreed that these preliminary standardization titrations are the most important step in the entire test. If these are properly done, setting up the tests proper is merely a question of accurate pipetting. When the preliminary tests give clear-cut results, then no trouble is encountered later from poor, peculiar, or inactive complement.

The principle on which the unit of complement is determined is as follows: In a series of test tubes an amount of sheep red blood cell amboceptor is added just sufficient to hemolyze 1 cc. of a 5 per cent suspension of sheep red blood cells together with this stated amount of the cell suspension. To the different tubes graded amounts of complement are added: thus, 1 cc., 0.8 cc., 0.5 cc., 0.4 cc., and 0.2 cc. of a 1-10 dilution of guinea pig serum. The total volume in each tube is made up to 3 cc. and then incubated in a water bath at 37° C. for about fifteen minutes. Practically the entire amount of hemolysis which is going to occur will have taken place in that time. The smallest amount of complement which gives complete hemolysis is the "unit of complement." After having determined the complement unit, then in another series of tubes are placed the unit of complement, 1 cc. of cell emulsion, and a varying amount of sheep red blood cell amboceptor. The minimum amount of amboceptor causing complete hemolysis is the amboceptor unit. The usual source of sheep red blood cell amboceptor is the serum of a rabbit which has been repeatedly injected with sheep red blood cells. In this way hemolytic antibodies are developed in the rabbit's blood.

The original antigen used by Wassermann was an extract in normal saline of the liver of syphilitic fetus liver. This deteriorates quickly and was soon supplanted by an extract of this material in absolute (ethyl) alcohol. Strong alcohol would hemolyze the red blood cells, and so the alcoholic antigen is diluted in normal saline in the proportion of 1 to 10 or 1 to 20. It has also been found that a similar alcoholic extract of normal human, beef, or guinea pig heart is just as satisfactory an antigen. Because of this there has been considerable criticism in the past of the non-specificity of the Wassermann reaction, since these non-specific, or non-syphilitic, antigens can be used. It is not necessary at this time to go into this point any further than to state that the results of the Wassermann test have established it absolutely as a diagnostic test for syphilis. The acetone insoluble fraction antigen of Noguchi is an alcoholic antigen made from the portion of the original alcoholic extract not solube in acetone.

The amount of antigen used in the original method was chosen more or less empirically. At present there are ways of accurately measuring the amount to be used. This will be discussed later. The patient's serum has to be heated to 56° C. in a water bath for one-half hour to "inactivate" it; that is, to remove whatever complement may be present, for complement is destroyed by exposure to this temperature for this length of time. If we are working with a measured amount of guinea pig complement, we must be certain not to introduce other complement and so destroy the quantitative relations of the ingredients of the test. There are also other reasons for inactivating the patient's serum, which can be discussed to better advantage later. It has been found that 0.2 cc. of a syphilitic patient's serum will give complete fixation of the complement used under the conditions of test.

With this outline we can now proceed to put the materials together and perform the test. The antigen, patient's serum, and guinea pig complement are placed in a test tube and the total amount made up to 3 cc. with normal saline. These are allowed to stand for a sufficient time under suitable conditions, so that the complement will be fixed to the antigen if syphilitic antibodies are present. At the end of this time we determine whether this has occurred by next adding the sheep red blood cells and their hemolytic amboceptor. If fixation of complement has occurred, then no complement is free and no hemolysis occurs. If no fixation has taken place, then we have hemolysis.

The above is essentially the way in which the original Wassermann is done; the principles un-

derlying it and the fundamental technic are those on which all modifications are based. The technic and methods have been steadily improved, so the test of today is considerably more reliable than it was when first used. Before proceeding to the final analysis of these, more discussion of some other factors is necessary.

There is such a thing as non-specific fixation of complement in the test. This may occur on account of some quality of the patient's serum or antigen, or because of a combination of these two. This is called "anticomplementary" action and the tests must be controlled so that this anticomplementary action will be discovered if present. It can often be eliminated. A control tube is always set up containing only patient's serum and complement, to which, after the proper period, amboceptor and cells are added. Complete hemolysis should occur; if it does not, then the patient's serum is anticomplementary and lack of hemolysis in the regular test may mean merely the non-specific anticomplementary action of the serum. Serum tends to become anticomplementary which has stood for several days, especially if in still contact with the blood clot and not inactivated—one-half hour at 56° C.—or when some hemolysis of the patient's blood has accidentally occurred and tinged the serum red. This anticomplementary reaction is at times removed by inactivating again just before performing the test. Therefore all sera should be inactivated immediately before setting up the test. Sometimes a specimen of antigen is anticomplementary by itself. This is easily controlled by using an extra tube with every set of tests, in which is put double the dose of antigen used along with complement and, later, the *hemolytic system*—this is the name for the combination of amboceptor and red cells. If double the dose of antigen used does not show anticomplementary power, then the single dose will not be anticomplementary.

Every antigen must be standardized and the unit of antigen is also standardized. With a known strongly positive syphilitic serum graded amounts of antigen (diluted in saline) are tested out with the regular complete Wassermann test beginning with 0.05 cc. and going up to about 1.5 cc. The smallest amount of antigen which gives complete fixation is the unit of antigen. After this has been estimated, the antigen dose used in the routine work should be at least two units. This two unit dose must not be more than one-fourth the anticomplementary dose to be sure of no non-specific fixation. Since the alcohol in which the antigen of today is dissolved may have an hemolytic effect on the red blood cells, one must be sure to exclude this possibility. This is done by determining the lytic action of the antigen on the cells by testing for this in a series of test tubes. Any potent alcoholic antigen, it will be found, will not hemolyze the cells in many times the routine test dose.

Alcoholic antigens are prepared for use in a very special manner. They are diluted in normal saline to a 1-10 or 1-20 dilution. The alcoholic antigen is first placed in a dry glass container and the required amount of salt solution is added extremely slowly while the mixture is continuously agitated. This results in a milky emulsion and is very important for good results. If the saline is added too quickly the emulsion does not form so well. The antigen must always be freshly diluted on the day of the tests.

It has been previously stated that a definite amount of complement must be used. This needs further elaboration. It has been found that two complement units will be completely fixed in the test by a positive syphilitic serum. Thus if 0.5 cc. of 1-10 dilution of guinea pig serum is the complement unit, then 1 cc. of this dilution is the amount added; that is, two units. As we have described, this complement titration is done by water bath incubation at 37° C. for fifteen to twenty minutes. Besredka, however, has shown that the true unit of complement can only be decided by much longer incubation; that is, if 0.5 cc. is the complement unit after twenty minutes' incubation, after several hours in the water bath it will be found to be about 0.25 or 0.3 cc. Some workers make this determination after twenty minutes' incubation, some by Besredka's method. Kaliski[2] uses the Besredka method and feels sure that thereby he never has an excess of complement and avoids false negative results. The twenty-minute method is the one generally used and is undoubtedly satisfactory.

The amount of hemolytic amboceptor in general use is also two units (of amboceptor). Here we come to a much discussed phase of the Wassermann technic. The reason for this is that, unfortunately, the majority of human sera contain natural hemolosins for sheep red blood cells. Two-tenths of a cubic centimeter of patient's serum, the amount usually used, may contain as much as two complete hemolytic units. As this is not destroyed at 56° C., it would be present in the test. If this is not taken into account, the addition of the routine two amboceptor units would give a great excess of this and would convert a weakly positive test, where the complement is weakly fixed, into a negative test. This excess of amboceptor has practically no effect in a strongly positive reaction; but in treated cases of

2. Kaliski: Quoted by Ottenberg.

syphilis this error could easily occur. This brings us to a consideration of how to take this natural hemolysin into consideration, and how to eliminate this possible error The ideal way would be to use an hemolytic system based on red blood cells of another animal than the sheep for which human serum has no natural hemolysin. This ideal cannot be reached, since a variable percentage of human sera has hemolysins for the red blood cells of all of the usually available animals. Human cells are the best from this point of view, but there are other disadvantages in human red cell systems.

A number of methods are in use employing the human hemolytic system. That called the Hecht-Gradwohl modification is probably best known. The limitations of this have been carefully tested out by Kolmer.[1] Kaliski's[2] method appeals to us as logically the best means of dealing with natural sheep red cell hemolysis. After the preliminary incubation of the mixture of serum, antigen, and complement, instead of adding amboceptor and cells at the same time, he first adds the cells, and then incubates for fifteen to twenty minutes. There is always in every Wassermann test a control tube containing only patient's serum and complement—no antigen—to rule out an anticomplementary action of the patient's serum. This tube serves Kaliski as an index of the amount of amboceptor to add. If complete hemolysis occurs in this tube, then not only is no anticomplementary action present, but at least two natural hemolytic units are present and no more amboceptor need be added to the other tubes of the test. If 50 per cent hemolysis occurs, then only one amboceptor unit is present and one more must be added and the test returned to the water bath until the rear tube shows complete hemolysis, which will require another fifteen to twenty minutes. In this way there is never an excess of amboceptor present. This error because of natural hemolysis is apt to occur also if sensitized cells are added, that is, cells sensitized by incubating them in bulk with sheep cell amboceptor. Here there is the same addition of the two amboceptor units, regardless of the amount of natural hemolosin present in the patient's serum.

The next important factor to consider is the temperature and time of the first incubation, that is, of patient's serum, antigen, and complement. In the original Wassermann this was for one hour in a thermostat at 37.6° C. This is the same as one-half hour in a water bottle at same temperature, for in a water bath the tubes become warm more quickly than in a thermostat. It has been found by numerous observers that this is not long enough for maximum fixation to take place; but it has also been found that longer incubation at 37.6° C. causes deterioration of complement which is incompatible with the test and gives false positive results. Therefore it has been observed that longer incubation at much lower temperature allows better fixation to occur and no deterioration of complement for a number of hours. The best temperature is 8° to 12° C. (ice box temperature). Four to six hours in the ice box gives the best results, and longer than this will give weakly positive results in negative sera, undoubtedly because of deterioration of complement (Owen and Martin, Ottenberg). Kaliski uses first one-half hour water bath incubation at 37.6° C. and then two to four hours in ice box. His results are undoubtedly reliable. More and more workers have discarded the water bath incubation and are only using incubation in the ice box. There is no doubt but that this is the method of choice and an appreciable number of weakly positive sera will be demonstrated by this method that will be missed by water bath incubation alone. There is an excellent recent article on this subject by Owen and Martin.[3]

The question of cholesterinized alcoholic antigen must be discussed. When this was first introduced it was found that a much larger percentage of positive results was obtained with it than with other antigens. This was thought an improvement in the Wassermann technic. It has since been learned that cholesterinized antigen has the defect of what may be called being too sensitive. It undoubtedly gives false positive results and it is definitely more serious to brand a patient as a syphilitic who is not than to miss an occasional positive case, deplorable as the latter may be. Ice box incubation with plain alcoholic antigen gives within 1 or 2 per cent as many positive reactions in known syphilitics cases as with cholesterin antigen. It must be remembered that up to now no technic has yielded 100 per cent positives in *tabes dorsalis* and general paresis. In questionable or known negative cases there are from 3 to 30 per cent more positives with cholesterinized antigen than with any other. It must be concluded that cholesterinized antigen gives false positive reactions and the consensus of opinion is that results from cholesterinized antigen alone are unreliable and should always be checked with other antigens.

Wassermann reactions are usually reported as follows: negative, one plus (+), two plus (++), three plus (+++), and four plus (++++). Four plus is the strongest positive result obtainable and means complete fixation and, in the absence of febrile complications or diseases, means active or latent syphilis.

3. Owen and Martin: Jour. of Laboratory and Clin. Med., January, 1920.

Three plus also indicates syphilis. Reactions less strong than this only have significance in untreated cases if they fit in with the clinical picture. One and two plus reactions are, however, of great value in guiding the treatment of a case.

Weakly positive reactions on the spinal fluid have more significance than the same degree on the blood. Some cases of syphilis of the central nervous system give positive reactions only on the spinal fluid and not on the blood.

We believe that all clinicians should have a certain amount of knowledge of the technic of the Wassermann reaction, so as properly to understand results and be able to interpret them and apply them clinically. By this knowledge the clinician is also able to decide whether the results are reliable or not. He should insist on Wassermanns done with ice box incubation and with at least two alcoholic antigens. Cholesterinized antigen results alone are not reliable and, where reports are given separately as results from different antigens, the clinician must interpret their significance, based on his knowledge of the technic of the test and his knowledge of the patient.

Modifications of the Wassermann technic using a human hemolytic system, such as the Hecht-Gradwohl, are capable of giving very delicate results, at any rate in a certain percentage of cases; however, one must make sure that they are done by a very careful expert worker.

Results Vary with Technic

A collection from the literature of results of Wassermann tests performed according to different technics shows discrepancies which occur in the results with different antigens and with different incubation temperatures.

Jacobstahl, in 1900, in 200 tests, found 2 per cent more positives with ice box incubation of one and one-half hours at 4° C. than at 37° C.

Guggenheimer tested 623 sera with incubation at 0° C. and 37.5° C. for one and one-fourth hours. Twenty sera showed a marked difference; twelve were positive only at 0°, eight only at 37.5°. The cases producing these sera were clearly luetic. These results are only slightly in favor of ice box incubation, but attention must be called to the comparatively short incubation period.

McNeil reports testing 466 cases at both incubator temperature and at 8° to 12° C., the latter for four hours. He obtained 10.3 per cent more positives with ice box temperatures than with incubation temperature. It is unfortunate that he did not give histories of his cases.

Coca and L'Esperence in testing 828 sera with incubation at 7° C. and at 37.5° C. found 203 positive by both methods; 28 were positive only at ice box temperature; and 13 positive only at incubator temperature. These results are again slightly in favor of incubation at a low temperature.

The results of Smith and MacNeal, especially interesting, are tabulated as follows:

Clinical Condition	Cholesterinized Antigen Incubator Fixation	Plain Antigen Ice-Box Fixation	Plain Antigen Incubator Fixation
110 cases of known syphilis	58% positive	75% positive	32.2% positive
43 cases probably syphilitic	65.9% positive	5% positive	36.3% positive
49 cases probably not syphilitic	40% positive	77% positive	1.6% positive
265 non-syphilitic cases	100% negative	100% negative	100% negative

These results, as noted by Owen and Martin, are difficult to reconcile. They indicate, however, that plain antigen with ice box incubation give a higher percentage of results in syphilitic and probably syphilitic cases than cholesterinized antigen. In probably non-syphilitic cases the very high percentage of positives with cholesterinized antigen seems to indicate non-specific results, which is the criticism that is made of this antigen.

Ottenberg states that plain antigen with ice box fixation gives the most delicate and accurate results. He finds that cholesterinized antigen cannot be used with ice box fixation.

Owen and Martin[3] in a very comprehensive article, from which we have taken much of the above data, give very interesting results. They found in five hundred known syphilitic cases 70.6 per cent positive reactions with plain antigen and four-hour ice box fixation, and 76.6 positives with cholesterinized antigen. This is a 6 per cent advantage in favor of cholesterinized antigen.

Five hundred cases clinically negative gave positive reactions with cholesterinized antigen in 3.8 per cent and with plain antigen and ice box fixation in one case, or .02 per cent. This case they class as a false positive. This false positive error can be seen to be much less than with cholesterinized antigen.

In 113 cases classed as doubtfully syphilitic the comparative results are again confusing. With cholesterinized antigen there were 32.8 per cent more sera positive than with plain antigen and ice box fixation. They conclude, however, that a positive reaction only with cholesterinized antigen in a case with a doubtful syphilitic history is in-

sufficient grounds for a positive diagnosis of syphilis.

Berghausen[4] used cholesterinized, alcoholic and acetone insoluble fraction antigens on two thousand sera and reports in detail the results obtained in 220 sera. Fixation was done in all by both water bath at 37° C. and ice box at from 0° to 2° C. He does not consider that his cholesterinized antigen gave false positive results which he states may have been due to his special sample of antigen and to the small amounts used. He utilized the method of Kaliski of allowing for the natural hemolytic amboceptor present in many sera. The percentage of positive results was consistently higher with ice box fixation than with water bath fixation with plain alcoholic antigen, ranging from about 6 per cent to 11 per cent. There were also a few more positive reactions with plain alcoholic antigen with ice box fixation than with cholesterinized antigen and ice box fixation. [It must be remembered that some observers claim that cholesterinized antigen should only be used with water bath fixation.] Berghausen concludes that simple alcoholic antigen with ice box fixation yields satisfactory results, that there is no evidence to show that ice box fixation causes false positive reactions, and that ice box fixation increases the number of positive reactions.

Wile[5] reports a very interesting series of cases. He has apparently discarded entirely, for the time being, all antigens except cholesterinized. He is much impressed by the results in his serological laboratory with the greater sensitiveness of cholesterinized antigen with sixteen hours ice box fixation over the same antigen with water bath fixation. The report is on 459 cases of syphilis in all stages, selected from thousands of tests. His results are carefully analyzed and cannot be given in detail. Two sets of figures are important. The ice box test gave 5 per cent more positive reactions in both treated and untreated cases of syphilis, and 50 per cent more in treated cases alone. Wile concludes that the cholesterinized antigen and ice box fixation are valuable modifications which render the Wassermann more sensitive. He claims that positive reactions obtained with this technic are rendered negative by intensive treatment in only a very small percentage of cases. Therefore, he questions the relationship between clinical cure and negative Wassermann reactions. This article is very stimulating and should lead to more careful work along this line. Unfortunately Wile did not compare other antigens with cholesterinized antigen.

Roderick[6] performed Wassermanns in 5,787 cases with cholesterinized antigen and with acetone insoluble antigen. He carefully controlled the antihemolytic tendency of cholesterinized antigen. The results differed in 47 cases—a very small percentage—in which the reaction was positive with the cholesterinized antigen. He was able to trace the history in 39 of these cases; 35 of the traced cases gave a positive history of syphilis. These figures are the best yet found in the literature justifying the cholesterinized antigen. Nevertheless, Roderick warns against using the cholesterinized antigen alone.

Blaivas[7] has reported on one hundred sera examined by the Wassermann technic and the Hecht-Weinberg-Gradwohl modification. Unfortunately, he does not mention what antigen and what type of fixation were used in the Wassermann technic. In spite of the fact that there were 5 per cent more strongly positive and 9 per cent more borderline positive results with the Hecht-Weinberg-Gradwohl technic than with the Wassermann, Blaivas concludes that the former method should never be performed alone but should always be controlled by the Wassermann. Seventeen of the one hundred sera were not suitable for the Hect-Weinberg-Gradwohl method.

To summarize the citations given it seems well established that the use of cholesterinized antigen in the Wassermann technic is unreliable in that it gives false positive results. Plain alcoholic antigen or the acetone insoluble fraction antigen of Noguchi with fixation for from four to six hours in the ice box at 4° to 8° C. is practically as sensitive as cholesterinized antigen and can be relied on *not* to give false positive results in non-syphilitic cases.

Prevalence of Syphilis

The following statistics from Spohr[8] give the percentage of positive Wassermann reactions found in several different groups of individuals. The most interesting and at the same time the most appalling are those given by Vedder[9] of the United States Medical Corps for recruits, cadets, and enlisted men in the United States Army. These results were obtained from men, presumably healthy, admitted to the Army. They serve as a more accurate index of the prevalence of syphilis in America than any other available statistics. Figures showing the prevalence of positive Wassermann reactions in hospitals or dispensary cases are of extreme importance in showing the possible relationship between syphilis and other diseases, but are not a proper index of the percentage of syphilis in the population.

4. Berghausen: Jour. Am. Med. Assn., 1919, lxiii, 996.
5. Wile: Jour. Am. Med. Assn., 1919, lxiii, 1526.
6. Roderick: Am. Jour. of Syph., 1919, lxiii, 1526.
7. Blaivas: Jour. of Laboratory and Clin. Med., January, 1920.
8. Spohr: Ohio State Med. Jour., January, 1920.
9. Vedder: War Department Bulletin No. 8, June, 1915.

Vedder[9] found 16.77 per cent of recruits were syphilitic at the time they entered the service; 16.08 per cent of white enlisted men, and 38 per cent of colored enlisted men were classified as probably syphilitic. Vedder estimates that about 20 per cent of the young adult male population of the class from which the Army was recruited are infected with syphilis. The technic of the Wasserman test used could not be found in the literature available.

Ecker[10] reports on 9,412 Wassermann tests made at the Serological Laboratory of Cleveland, Ohio. His results were from cases with a suspicious history or obscure symptoms. The figures therefore do not determine the percentage of syphilis in the entire population of Cleveland. The technic of the Wassermann test used is not given. Ecker found 23.71 per cent positive among the males and 24.99 per cent among the females.

The following show the percentage of positives when routine Wassermanns were performed at various children's clinics:

Epstein, at Prague, 33 per cent of 236 new born infants; Blackfan, Nicholson, and White, 2 per cent of 101 patients; Holt, 6 per cent of 178 hospital children; Elliott, of Glasgow, 10 per cent of 130 children; Children's Clinic, at Prague, of 2,533 infants 5.7 per cent were syphilitic; Whitney, from a San Francisco Hospital, 2.9 per cent of 915 children; and Churchill and Austin at the Children's Memorial Hospital, in Chicago, 3.3 per cent of 695 cases. The Wassermann technic used in these tests is not stated in the literature available.

Spohr performed routine Wassermann tests on 1,840 children admitted to the Children's Hospital of Columbus, O. Of these 5.16 per cent were positive, and 4.23 per cent gave weakly positive reactions. In only one case was syphilis acquired after birth. These tests were performed by the Craig Modification, with the use of cholesterinized antigen and human corpuscles. The figures should be interpreted in light of this and are probably higher than plain alcoholic antigen would have given. They are very valuable, nevertheless.

MEDICAL RESEARCH COUNCIL

By Our London Correspondent

THE value of medical research was conclusively proved during the war, and in Great Britain so evident were the results from this form of investigation that the decision has been reached to enlarge the scope of the Medical Research Committee which has done such good work in the past few years. The Medical Research Committee has been transformed into the Medical Research Council with an enlarged sphere of duty and with greatly increased responsibilities. The newly formed Medical Research Council with an enlarged sphere of duty and with greatly increased responsibilities. The newly formed Medical Research Council will perform its functions under the supervision of a Committee of the Privy Council, which will consist of Mr. Balfour, the Lord President of that Body, the Minister for Health, the Secretary for Scotland, and the Chief Secretary for Ireland. Accordingly, the Medical Research Council becomes a permanent sub-committee of the Privy Council, and under its governing body can enter into all contracts, can hold personal property, and dispose of same.

Among the main points of interest to medical men in the constitution of the new body, two are especially significant: (1) the Medical Research Council obtains access without intervention to the Minister directly associated with its work, and (2) the advice of the Royal Society is to be taken in respect of the personnel of the Council. The first Council consists of the existing Medical Research Committee and is constituted as follows: Mr. C. T. Bond, F.R.C.S., consulting surgeon to Leicester Infirmary; Prof. William Bullock, F.R.S., professor of bacteriology in the University of London; Dr. I. R. Elliott, F.R.S., physician to the University College Hospital; Mr. William Graham, M.P.; Viscount Goschen; Dr. Henry Head, F.R.S., Prof. Gowland Hopkins, F.R.S., professor of biochemistry in the University of Cambridge; Sir William Leishman, F.R.S., director of pathology, A.M.S.; Prof. Noel Paton, professor of physiology in the University of Glasgow; and the Hon. E. F. Lindley Wood, M.P. Two of the members of the Council, having seats in either the House of Lords or the House of Commons, will be able to render a first hand account of the Council to Parliament. Three members of the Council will retire at intervals of two years, and appointments to their vacancies or to any other vacancies which may casually arise, are to be made by the supervising Committee of the Privy Council after consultation with the existing body itself and with the President for the time being of the Royal Society.

This recognition of the Royal Society as the body definitely constituted to advise the Government in matters pertaining to science is timely. The Royal Society has been called upon frequently to fulfill a function of this character and its recent work with respect to the food supply during the war is still green in the memory. But among medical men there has developed a feeling lately that the best knowledge of science has not always been at the disposal of Government Departments. However, with regard to the new Medical Research Council this objection should not hold good.

IVY AND SUMAC POISONING

The wide prevalence of certain species of plants belonging to the Rhus or Sumac family, and the fact that absolute immunity to the action of Rhus toxin does not exist, emphasize the importance from a health standpoint of learning the prominent characteristics of these plants, their leaves, fruits, winter buds, and habit of growth so that they may be avoided.

An article on "Ivy and Sumac Poisoning," by E. A. Sweet, Surgeon, United States Public Health Service, and Dr. C. V. Grant, Bureau of Plant Industry, Department of Agriculture, in *Public Health Reports*, February 27, 1920, describes minutely the features of the plants to be feared, the varying degrees of susceptibility to the poison, the means of exposure, the clues to the character of the disturbance, methods of prophylaxis, and the management of cases.

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

MONOTONY AND FATIGUE IN SHOP AND OFFICE

THE importance of psychological and physiological research in relation to industrial welfare is now recognized by the medical profession. The monotony of certain trades and industries is largely responsible for the ill health and discontent that prevail among the workers in these trades and industries. It is an obvious fact that no machine of metal, however well made, will work properly unless it is kept clean and oiled and is run under suitable conditions generally. In order that it may work efficiently, the human machine requires far more than mere good hygiene and sanitation, essential as these are. That complex machine, the human body and mind, is patently much more delicate and much more sensitive to its environment and consequently stands yet more greatly in need of care and attention if it is to perform its functions to the best effect. It is not enough that it is well oiled and cleaned, that is, is provided with plenty of suitable food and works under healthy conditions.

The psychological and physiological aspect must be considered as well. Fatigue and monotony of labor must be avoided as far as is possible. The worker must perform his daily task in comfort and in circumstances in which sufficient variety exists to dispel or palliate the gloom of monotonous toil. It is only recently, however, that this phase of the matter has been considered. Until comparatively lately little thought has been bestowed on the character of the conditions required for efficient working, and even less on seeing that they were provided in factory, workshop, and office.

It is with the object of studying these conditions, systematically and scientifically, and of securing their observance in practice, that the proposal to found a British National Institute of Psychology and Physiology as applied to industry and commerce has been advanced with the support of prominent leaders of industry and of well known psychologists and physiologists. Among the latter may be mentioned the names of Dr. G. S. Myers of Cambridge, Prof. C. S. Sherrington of Oxford, and Prof. E. H. Starling of London University.

Of the ways proposed to attain this object, one of the chief is the establishment of a well equipped laboratory or laboratories for research into various occupations in order to determine the conditions necessary to get maximum output with minimum fatigue and discomfort to the worker, such as the elimination of unnecessary movements, and to study the causes of mental and muscular fatigue and the methods for reducing it. Tests would be made in the laboratory for the purpose of establishing standards by which workers could be selected for work for which they were best fitted, mentally and physically. These standards would enable parents and after-care committees to be advised as to the best vocations for children, and should thus eliminate much waste of time at the outset and prevent a good deal of the discontent which arises when a worker finds out too late that an unsuitable occupation has been chosen. The facts established by research would be collected and classified, and from time to time published in such form as to bring out their practical value.

Another function of the institute would be to provide training courses and lectures for investigators, managers, foremen, and welfare workers in the practical applications of psychology and physiology, and it would undertake investigations at factories and offices in relation to any special problem. It would study the conditions that tend to promote the health, comfort, and welfare of the worker and, also, the psychological relations between employers, manager, foreman, and worker, with special reference to securing harmony and cooperation. It would further undertake propaganda work among employers and employed and cooperate actively with organizations of both, for the furtherance of national unity and prosperity. It is needless to state that in order to carry out this program in an adequate and a satisfactory manner a considerable amount of money will be required. The maximum income deemed necessary is £6,000 for the first five years, but it is hoped that an appreciably larger sum will be obtained so that the Institute may be able to start its work on a scale commensurate with the problems with which it will have to deal. A laboratory will be established in London and, later, in such of the provincial towns as may seem desirable, and it is intended to secure the services of a number of experts in psychology and physiology who will give their whole time to the work. After five years it is considered that, to a large extent, the Institute should be able to support itself out of the fees which it would charge for its services, as in making mental and physical tests and giving advice as to the suitability of individuals for particular occupations. But it would not work a profit and all its income would be applied in promoting its objects.

Dr. C. S. Myers, who is probably the foremost psychologist in this country and who is an enthusiastic advocate of the application of psychology to commerce and industry, and who is an ardent supporter of the scheme sketched above, writing in the *London Times* of April 8, 1920, adds the following notes regarding the proposed National Institute of Psychology and Physiology applied to industry and commerce:

(1) The Institute will have very close relations with the Industrial Fatigue Research Board, which is giving

it unanimous support. There will be neither overlap nor rivalry between them. They will, it is hoped, share a common laboratory and library. The work of the Fatigue Research Board will continue to center about fatigue in different industries, while the proposed Institute will determine in individual factories and offices the best methods of reducing fatigue and monotony, of selecting workers for the occupations for which they are mentally and physically best fitted, and of distributing the hours of work and rest. It will provide training courses in industrial psychology and psysiology, study the psychological relations between management and labor, and spread the general results of its work.

(2) It will be run without profit and its investigations will be undertaken by a scientifically trained body of workers. Thus, it will come to take up a position in regard to the human side of industry similar to that occupied by the National Physical Laboratory on the mechanical side.

For the purpose of efficient coordination of research, a scientific committee is being formed of the leading psychologists and physiologists throughout the country who are especially interested in the industrial and commercial application of these sciences. The Institute will give grants to laboratories in universities and technical colleges where investigations on the human side of labor require assistance. The personal well being of the industrial or office worker is manifestly of the first importance, and, of course, psychology and physiology enter largely into the question.

Otto P. Geier, M.D., President of the American Association of Industrial Physicians.

If a person works to fatigue due to excess in duration of labor in specialization, repetition, strain, or speed, this person cannot give of the best. A monotonous task is probably the most tiring, and the efforts of the psychologist will be bent towards alleviating the situation from this point of view and also from all the other standpoints which come within its province. Perhaps preventive psychology will be found of the greatest use. Its value, or rather the value of the advice given by its exponents, with regard to the choice of a trade or industry, is too obvious to need emphasis. It is the square pegs in the round holes which are responsible for a great deal of bad work and for much of the discontent which exists among the working classes. So far as Great Britain is concerned these matters apply to between 130,000 and 150,000 factories in which twelve million people spend one-third of their lives, besides a vast number in offices. The proposed establishment of a National Institute of Psychology and Physiology is not only a long step in the right direction but is a proposal marked by sound common sense and will make immediately available for practical uses the studies, both of the experimental laboratory and the direct observation of workers and working conditions. Waste of time and the unnecessary fatigue which may be due to ignorance will become inexcusable.

London Correspondent.

THE GROUP INDUSTRIAL SURGICAL HOSPITAL

By A. MONCRIEFF CARR, M.D., United States Public Health Service, Philadelphia, Pa.

By a group industrial hospital is meant a hospital serving a large or small group of industries, preferably of the same type. Few single industries can afford to maintain establishments and employ the best surgical personnel and necessary skilled help required for adequate service. So we have a few larger industries fairly well served, but innumerable smaller industries, not being able to secure the best surgical skill or hospital care because of expense of maintenance, have to take what they can get, to the detriment of the injured.

At present the great mass of the injured are treated in general hospitals and no special care is given. The injured man is seen by the "visiting" or by the plant physician, and administered to by the intern, whose treatment is very largely that of experimentation. Often the visiting surgeon is a general surgeon and knows little of modern bone surgery or other industrial surgery, and nothing at all of industrial relations. The nurses are pupils and do not appreciate the problem of the injured worker. From a personal experience, as chief resident in a hospital of a large manufacturing center, I know that it was a common thing among the staff and nurses to regard the industrial case as a nuisance.

A reasonable and practical solution of the problem would be a central hospital, with outlying dressing or emergency stations, organized for prompt, efficient service, serving a group of industries, emergency and surgical; cooperative and follow-up, reconstruction and rehabilitation services, with a selected, Trained personnel, developed on a unit system for the special needs of the group, should be features of the hospital.

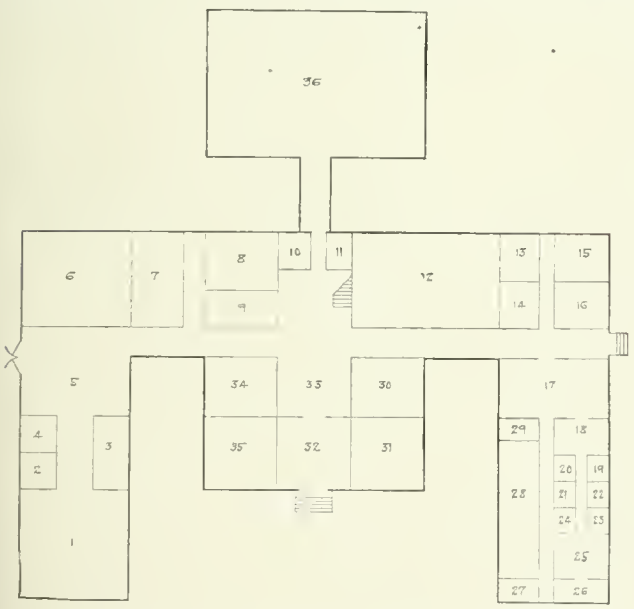
In connection with the planning of a central hospital, the importance of a survey of the industrial group should be emphasized. Types of accidents should be estimated, comparison made with other groups, so that an intelligent plan may be perfected. For instance, a survey of New York's lower west side would reveal an immense amount of shipping, which spells serious accidents and infections; the congestion of traffic points to the need of establishing a central "base hospital" with outlying "dressing stations" on the "front line."

Before the various departments of the hospital are taken up in detail, it is well to call attention to the keynote of success in the salvation of the industrial cripple. This may be summed up in the term "personnel." Readers will perhaps tire of the seemingly unnecessary description of the requirements of the chiefs of the departments, herein recorded, but, heretofore, too little attention has been paid to the personal characteristics essential in the specialty of industrial surgery.

The chief surgeon is first an industrial surgeon, and preferably, one who has had experience in modern war surgery which will enable him fully to appreciate after-care, aside from the actual surgery done. As the military commander studies the daily life of the soldier, so should the industrial surgeon be thoroughly conversant with industry. It is strongly urged that the man selected for the key position of chief surgeon be a socially minded young man of executive ability, whose reputation as a surgeon can be proved by his record of successful cases. His assistants should be chosen as much for their ability to cooperate as for their natural talent and experience.

The industrial nurse should be a graduate, and not a probationer or even a pupil; neither of the latter has had sufficient experience either of life or industrial work to appreciate the workers' problem, or to realize its importance. Some will immediately say that graduates will not do ward work. Yes they will, if properly paid!

Lastly comes the question of salaries, and one of the most uncertain. It is fair, however, to say that salaries paid to fulltime men should compare favorably



First Floor, Group Industrial Surgical Hospital. 1. Disposition or observation ward. 2. Ward toilet and bath. 3. Patients' property. 4. Admission baths. 5. Admitting room. 6. Dressing room and records. 7. Apparatus repair and splint shop. 8. Ward and operating room supplies. 9. Pharmacy. 10. Bed elevator. 11. Passenger elevator. 12. Offices for chief of follow-up and three assistants. 13. Genito-urinary clinic. 14. Ear, nose and throat clinic. 15. Dental clinic. 16. Eye clinic. 17. Waiting room. 18. History room. 19 to 24. Dressing rooms, (men's). 25. Examining physician. 26. Laboratory. 27 and 29. Toilets. 28. Women's examining department. 30 and 34. Clerical force. 31. Conference room. 35. Record room. 32. Information and telephone. 33. Waiting room. 36. Engine room and kitchen.

with other business. A surgeon who nets $15,000 a year in practice could not be asked to accept less as chief surgeon; his assistants would be paid according to ability, experience, and responsibility. Nurses' salaries should be proportionate to that paid in private work, modified by the fact that the employment is steady.

It is the purpose of the following plans and accompanying diagrams to suggest a workable basis which can be modified, or added to, according to the community's needs. However, the need of a change from the usual type of general hospital, as now established, to one that more nearly fits the need of an industrial group, is indicated. What is omitted in the written description, such as office equipment and arrangement, is indicated in the diagrams; detail is left to those concerned in the final perfecting of such a hospital, the plans presented here being suggestive only. The departments are taken up in order of their importance and logical sequence, from the admission of the patient as "a case" to his departure as a well man.

The receiving department is the reception room of the injured man's home for the period of his disability. The majority of receiving rooms, even in the modern hospitals, have a gloomy and depressing atmosphere, aside from the architecture, and the patient's first impression is often lasting. From the time the case is taken from the ambulance or seen by the admitting physician until he is sent home, he should be made to feel that the best that can be done is being done, in the most efficient manner, with courtesy and kindness. No physician or nurse that has not been trained in receiving ward work has any business in this most important department; and only those who have tact in dealing with working people should be in charge here.

The record system should have brevity as its symbol; only essentials should be put down. The special dispensary card should have the following essential facts recorded: name, address, home and factory, nearest kin, social state, name of foreman, occupation, time of accident, provisional diagnosis and temporary treatment. This card should be sent to the ward with the patient, with the additional data of: bath given, property listed, tetanus antitoxin administered, and statement as to whether the case is infected or clean.

Receiving Department Work Important

In the arrangement of space in most general hospitals, little or no attention has been paid to doctors' or nurses' suggestions as to the convenience or even necessity of proper apparatus in proper places, or of space for turning corners, or adequate lighting. Heretofore an architect has been asked to draw a plan based on his knowledge of previous plans, and he has often disregarded suggestions made by those most concerned in the future service of the building. Many hospitals have a receiving department, ment seemingly an afterthought it would seem from the appearance of some of them. It is suggested that this department be given consideration from a practical standpoint.

With the chief surgeon a full-time man, it is possible for him to see immediately the cases brought directly to the hospital, or sent in by outlying stations, and pass judgment on the further disposition of the patient, as to proper ward placement and initial treatment. A ward of sufficient size to meet emergency needs should be established in connection with the receiving department. As it is now in most general hospitals, the "case" is seen by the intern, and the most frequent expression heard is: "I guess we'll put him in such and such ward." Sometimes it has been half a day or whole day before the chief surgeon has seen him. The routine of this department should be carefully and minutely outlined, with no openings for mistakes. Lastly, a routine administration of tetanus antitoxin should be a steel-bound rule, neglect of which should mean immediate dismissal, as it meant court-martial in the Army overseas.

Examining Department

It would be an insult to present day knowledge not to include in such a program a department for pre-employment and periodic physical examinations. The arrangement of examining, waiting, dressing, and record rooms

should be such as to enable one doctor and attendant to examine a reasonable number of applicants in a short time. If the amount of this work proved to be very great, a full time examiner would be required, and for the best results it has been found that better records are made by one doing this work exelusively, instead of by members of the staff taking turns at it. In this department could be placed any special clinics, *i. e.*, eye, ear, nose and throat, genito-urinary, and dental, as indicated by the survey, and the policy of the management.

Ambulance Service Provided

It would be good for every ambulance surgeon and driver to ride in an ambulance—as a patient! The longer the ride, the sooner would be brought about the necessary reform of almost every present ambulance service. Most ambulances are driven as if the patient were on a joy ride, and the pavement of glass instead of cobbles and trolley bunkers. The present qualifications of the usual driver are knowledge of streets, and experience in driving. It is maintained, however, that every hospital should be equipped with up-to-date and comfortable ambulances and should employ a personnel trained in handling sick people. If there are outlying stations there should be an ambulance to serve each one, supplementing the central service.

The Surgical Department

In considering the operating department, one cannot get much further than principles. The scope of industrial surgery is largely fracture work, repair of large wounds, which includes nerve and tendon injury, or a combination of all these.

A well known, successful industrial surgeon, who was also a chief surgeon, stated that he had had extremely few infections in fifteen years of experience. He said the reason for his success was partially due to his constantly keeping in mind the maxim of that master mind and hand, John B. Murphy, that the way to prevent infection is to keep away from infection.

At any rate, the thought seemed a good one, and from it comes the idea of separate operating rooms for infected cases and clean cases, respectively; and, by separate is meant operating room itself, sterilizing room, supplies, instruments, anesthetizing room, scrub-up room, etc.

The size, arrangement, equipment, operating routine, cannot be given space here, but a few salient points regarding surgical equipment would aid in making things run smoothly: Having two full sets of surgical instruments; two teams of surgical nurses; anesthetizing on the operating table; swinging doors done away with, and electrically operated sliding doors substituted; bacteriological tests made for slips in surgical routine; bacteriological tests in sterile routine of gauze and sutures; location of operating rooms convenient to wards; and heated passage to and from operating room and ward.

In consonance with the idea of separate operating rooms for infected and clean cases, it follows that separate wards should be considered.

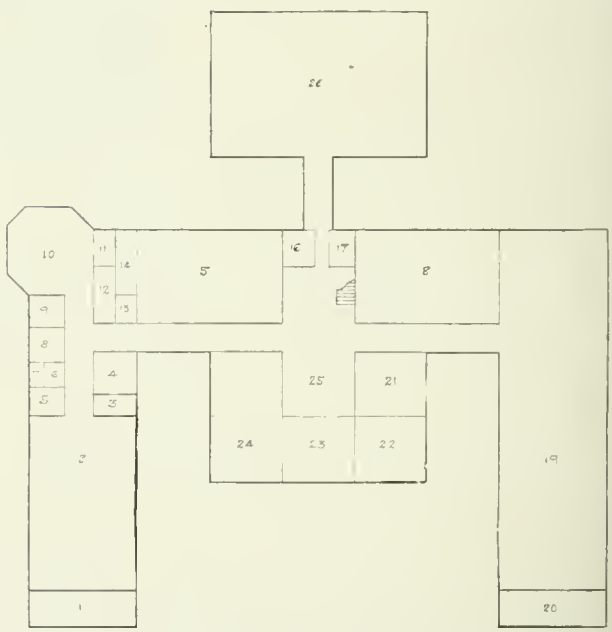
When a case adjudged clean develops infection, it should immediately be moved into the infected ward, and all the dressing instruments thoroughly disinfected and sterilized; the infected case should be treated as a danger to other patients. Grouping of similar cases not only is easier for the nurses, but the psychology of it, in regard to the patient-employee, is sensible; this prineiple could be followed with benefit throughout the entire time of hospitalization.

As to capacity and arrangement, referenee is made to diagrams. The ward of ten or twelve beds is easier to manage than one of twenty or twenty-four beds, which is usual even in many modern hospitals, and the work of the nurses in a small ward is more effective. This department would be incomplete without a plaster room with full anesthetic equipment; the splint and fracture apparatus room should not be attached to the ward, but should be an entirely separate room near to the repair and carpenter shop. A master carpenter or cabinet-maker, capable of making every known splint or its modification, on short notice, should be in charge. There should be an abundance of every possible appliance.

It is a question whether a solarium should be attached to each ward, or whether a solarium should be built to accommodate all the hospital cases. Certainly a smoking room, equipped with necessary amusement paraphernalia, should be a part of each ward.

Ward for Medical Cases

If the survey reveals a sufficient number of medical cases to necessitate a special ward, its construction need not differ materially from the other, except the provision of two quiet rooms. It need not be as large as the surgieal wards. If there is a venereal clinic, a separate ward should be arranged for; but this depends on the policy of the management.



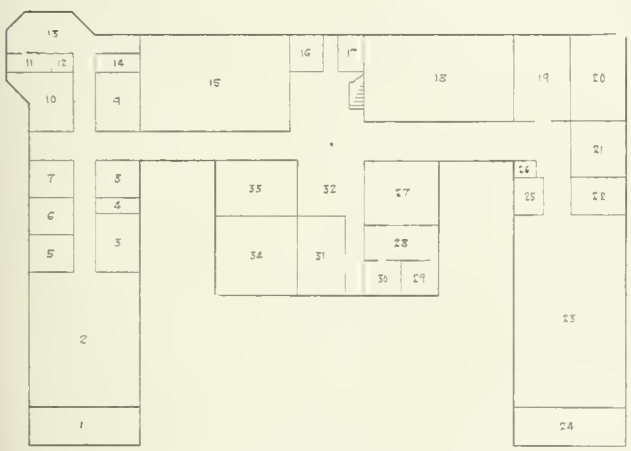
Second Floor, Group Industrial Surgical Hospital. 1. Solarium and smoking room. 2. Clean surgical ward for 12 beds. 3. Nurses records, etc. 4. Dining and serving room. 5. Ward toilet. 6 Linen room. 7. Laboratory nook. 8. Plaster room. 9. Anesthetizing room. 10. Operating room with automatic sliding doors. 11 Scrub-up. 12. Sterilizing. 13 and 14. Surgeons' smoking and dressing room. 15. X-ray and laboratory departments. 16 and 17. Elevators. 18. Offices of chief nurse and assistants and nurses' rest room. 19. Infected ward, homologous to clean ward. 20 Solarium. 21. Reference library and conference room. 22. Offices of chief surgeon and assistants. 23. Office of superintendent. 24. Case records, clerical force and bookkeeping. 25. Waiting room. 26. Dining rooms for all personnel.

Laboratory and X-Ray Department

Laboratory work could be largely confined to bacteriological work, with necessary routine tests when called for. Owing to the nature of the work in such a hospital, every facility for research work in bacteriology and serology should be provided as an aid to the surgeon. Emergency sera could advantageously be kept on the wards and in the receiving ward, and a stock supply in the central laboratory. A resident pathologist is pre-requisite.

The x-ray is of course an indispensable part of an industrial hospital. However, if a bedside outfit were part of the equipment, it would add considerable efficiency and obviate a great deal of delay and discomfort to the patients. More attention should be paid to progress reports in this department, leading up to a final report before the patient leaves the hospital, or even a year after, for review of the case at the staff conference.

In this department comes the second stage of a man's return to work, and in most cases it is the hardest for him. It is also difficult for those who have his care. So much has been written on the psychology of the cripple and the treatment of his mental attitude during convalescence, that those interested are referred to the many articles on reconstruction published during the war. However, some things are necessary besides mere equipment; "personal touch" should be considered the most useful asset in this department. The convalescent industrial case is human and during the period of compulsory inactivity he needs encouragement; the interest taken by someone who understands is much appreciated. Nowhere can the convalescent receive more sympathetic encouragement to get back on the job that in this department, and the selection of a personnel under the direction of a surgeon experienced in this work should be considered of paramount importance.



Third Floor, Group Industrial Surgical Hospital. 1. Solarium and smoking room. 2. Medical ward for eight beds. 3. Ward dining and serving room. 4. Linen closet. 5. Ward toilet. 6. Nurses' records, etc. 7 and 8. Quiet rooms. 9 and 10. Semi-private rooms. 11 and 14. Private baths. 12. Linen closet. 13. Sun parlor and smoking room. 15. Residents' quarters. 16 and 17. Elevators. 18. Gymnasium, machines, electrical apparatus. 19. Recreation and smoking room. 20. Vocational work. 21. Dining and serving room. 22. Nurses' records, etc. 23. Convalescent ward for 12 beds. 24. Porch. 25. Ward toilet. 26. Linen room. 27. Massage, whirl and pool baths. 28. Rest room. 29 and 30. Douche and light baths. 31. Clerical force. 33 Offices for chief of reconstruction and assistants. 34. Residence recreation.

The personnel should consist of a surgeon accustomed to handling industrial workers, having a fair knowledge of many of their individual jobs, and able to demonstrate the necessary treatments in each case. He should be allowed to select his own workers according to their ability, personality, and willingness to cooperate; the number of workers should be sufficient to care for easily, without haste, all the cases under consideration.

Physio-therapy includes: the application of massage, electrical and manual, hot and cold water, baking, muscle re-education, and gymnastics. The arrangement of the various rooms should be determined by the order of their use. Massage tables, baking apparatus, light and whirlpool baths, with electrical attachments at each table for any necessary applications of electrical currents, can be in one room; machines and appliances for muscle re-education and gymnastics, require a room by themselves. If a department of hydrotherapy is required, a special douche room and vapor or light bath compartment, with connecting rest room, is essential.

The card system here is most important as a progress record, and should contain: surgical history, diagnosis and proposed treatment; all measurements of motion, strength, and other notes of progress should be carefully recorded for final review at weekly or monthly conference, both by the surgeon in charge of the case and by the chief surgeon.

The Commissary Department

A hungry soldier cannot fight efficiently, and neither can efficient hospital work be done on an inadequate and tasteless diet. If the story of a nurse who has had eating experiences in over twenty hospitals, in twenty different states, is to be believed, then the food department in most general hospitals is very often the most poorly managed. It would be hard to put one's finger on the exact cause of the usual poor commissary existing in most hospitals today; some say graft, some inefficiency in buying; some blame the cook, and some the dietitian. One does not hear complaints about the majority of good hotel dining rooms, though the problem is about the same. Hotels manage their kitchens on a profit and loss basis, and give service accordingly; hospitals should assume this attitude, at least, and profit would accrue from satisfied personnel and patients, besides an actual saving from efficiency.

A slight change in the usual system now existing is suggested. It is proposed to put in charge a hotel-trained chef, who will have entire authority in preparing the food. A nurse who has had training in dietetics will consult with the chef in regard to all food for the patients, and prescribe the menu.

The need and advantage of re-training an injured workman has been shown to be an essential part of any scheme for reconstruction, by the splendid work done during and after the war, in Europe and in this country. There are numerous plans from which to choose, and their application in the group industrial hospital is easily accomplished.

A few essential principles should be considered for effective work: vocational training, either along the line of the patient's work or in some similar trade, should begin in convalescence, even before the patient is out of bed; the book and chart work can be quite easily started in the ward. Before the first week is ended, an injured man should be surveyed, an estimate made of his probable disability, and also of his capability, classification recorded, and the training offered him. It is more reasonable to emphasize an injured man's assets rather than his liabilities, and the mental attitude of the usually discouraged cripple when guided along the proper channels, not only gives him an opportunity for a "comeback," but puts him in such an environment that he wills himself into getting well and back on the job.

There are three main classes into which most injuries fall, and in some cases the man requires re-training:

(1) Fractures and sprains of upper extremities.

(2) Fractures and sprains of lower extremities.

(3) Contractures, nerve injuries and muscle atrophy.

There might be added another class to include medical cases. These are basic, and disabilities can be rated under these heads for all practical purposes. After a man has had a primary training in the hospital school, there could be a system of transfer to one of the workshops of

the group, where he can finish the practical work. Such a department would call for the careful supervision of the surgeon in charge of reconstruction; teaching can be done by men or women trained in such work.

Quartermaster's Department

This department can be divided into two depots, one for ward, operating room, and dispensary supplies, and another for general supplies.

(1) *Hospital Supplies.*—A pharmacist, with an assistant who is a graduate nurse, should be in charge of hospital supplies. These would include drugs, chemicals for disinfection, laboratory, ward and operating room apparatus, and other necessary material, such as raw gauze, instruments, etc.

(2) *General Supplies.*—These would include all supplies for kitchens, laundry and office. This depot should be on a strict business basis and have a thorough checking system, and managed by a storekeeper.

Follow-Up or Social Service

This department should be an integral part of the hospital, and the idea of charity, so general in hospitals at present writing, done away with. The same care should be used in the selection of the personnel of this service as that of any other department, basing it on experience and training in industrial relations, personality, and enthusiasm for the work.

The work could be divided as follows: (1) Dispensary. (2) Wards. (3) Outside.

These are equally important. The record work would include: records of all patients, in the hospital and discharged, with a brief summary of hospital record; weekly or monthly report, if called for, of all patients discharged within one year or longer; weekly ward reports; family follow-up reports; vocational reports; employment reports.

A chief with two assistants, one for the dispensary and ward service and one for the outside work, empowered to select the remaining personnel sufficient for effective work, should be placed in charge and allowed to manage the department without interference.

The record system should have brevity and simplicity as its features. One of the essentials of all follow-up work is a clear history, and an interpreter is an absolute requirement in this country of polyglot languages, and is not only useful in this department, but frequently very necessary to the surgeon.

Just a word on outside work: While working with the War Risk Insurance Bureau, it was found that a man would be willing, almost always, to go to the hospital or sanitarium, or in training at the Federal Board, provided his family was taken care of. It would seem, therefore, that if, while in the hospital, an injured man knew that his compensation was paid promptly, and that his folks had enough to eat and wear, the bond of loyalty to the hospital and his employer would be strengthened; and he would, forever after, be a booster for the service. Besides this, he would be greatly encouraged to make an extra effort towards a complete and rapid recovery.

The Record System

If at all possible, a complete card system is advised, doing away with the long history and treatment sheets which continually inspire verbosity on the part of historian and nurse. The system of card index is universally satisfactory, and, in the case of a special hospital where the history is not a part of a teaching system, it would more than prove its worth in compactness, durability, and efficiency.

In an industrial hospital most of the cases are surgical, and do not require the taking of any lengthy previous history, but, nevertheless, do require certain essential facts to make them complete. A few of them can be mentioned here:

(1) How, when, and where accident happened. This should be carefully recorded, and, if necessary, corroborated by witnesses, better by the foreman.

(2) Physical examination of stripped patient to include any other injury or any complication aside from chief complaint or disability.

(3) Daily notes of progress and treatment made by surgeon in charge.

It is unnecessary to enumerate details concerning the card used; the above are points noticed in review of numerous industrial surgical histories, conspicuous by their absence. The importance of a record system that really records is inestimable—establish a good record system before the hospital is built; otherwise a litigation may start which depends on one small record that is not complete—the cost will wipe out a fund sufficient to establish a bed in perpetuity.

The purpose of industry is production for profit, and a great deal of the profit depends on the physical fitness of the real producers—the workers.

Heretofore there have been three main parties concerned in the welfare of the employee—the worker, the manufacturer, and the accident insurance company. These three should get together on a business agreement, and each receive an equal share of the benefits. The worker would receive health service worthy of the name, and none is too good; the employer would see an increase in production through a healthy and contented working force and a lessened labor turnover; the insurance company would profit accordingly.

It seems a destructive attitude for one class to criticize another, and certainly does not get anywhere in solving the problem. The writer firmly believes that no final adjustment of things will be reached until the three classes get together on an equal basis, each considering the other necessary to the plan. Perhaps the idea is too new, or sounds too idealistic for these strained times, but eventually there will be an adjustment of this problem and some such plan will be the working basis.

There are some things that cannot be done, and one of them is the prompt and efficient organization of group hospitals, with all their ramifications, by the State or Federal Government; somehow or other, politics creep in, with its consequent inefficiency and endless red tape, which has the inevitable result of slowing up the machinery. The competition which would be stimulated by the group plan should keep up a better standard of efficiency. Legislation is a necessary aid, but the better plan is to prove that good service is the only right way, and not to compel those concerned to toe the line because of the law. This is not speaking in disparagement of the United States Public Health Service; however, this splendid organization is hindered at every turn by lack of funds for the developing of present work, such as hospitals for sick soldiers. It already has too much to do.

The establishment of group industrial hospitals, as outlined above is a practical and reasonable answer to the solution of the problem of the industrial cripple, injured by accident or disabled by some other health hazard.

In conclusion, what benefit will be derived from work done during the great war, both with the army at the front and in industry at high pressure at home, if not applied for the good of industry at large?

WOUND INFECTION IN INDUSTRY*

By DRURY HINTON, M.D., Medical Supervisor, Philadelphia Works, E. I. DuPont de Nemours & Co.

THE suggestions made in this paper are based on experience gained as an intern with Dr. George W. Crile, at the Lakeside Hospital, Cleveland, O., on twenty-three months service in France with a special assignment upon the secondary closure of wounds during which time some three hundred were treated; upon one year's experience as instructor in the Surgical Dispensary of the Hospital of the University of Pennsylvania; and one year's experience as an industrial surgeon, with the Dupont Company, in which last experience the method successfully applied to the injuries incident to the industry of war, were employed with satisfactory results to the injuries occurring in the industries of peace.

The Defence Against Infection

In war industry the surgeon's duty is to return the man promptly to the firing line, in peace to the working line. All wounds are potentially infected, but heal promptly if made and kept surgically clean. In war, there was some excuse for infection, for often there was a considerable lapse of time between the injury and the first adequate surgical treatment. In industrial surgery there is no excuse for infection, since there the lapse of time is negligible as the surgeon on duty should be prepared for immediate action.

The unbroken skin is the first line of defense against infection. Blood circulating freely through the capillaries is the second line, and is the most potent antiseptic known to science.

A scratch or superficial cut should be washed with an antiseptic because there is no dead tissue, and the antiseptic reaches every part of the wound. Thereafter a dressing is needed to protect against further infection and repeated slight trauma, such as may occur from rubbing or bending motion at a joint. Local splinting may be needful, but rest of the part is not desirable since use stimulates the circulation and hence accelerates healing. The best antiseptic for scratches and superficial cuts is Dichloramin-T, the best dressing is a few layers of sterile gauge, strapped on with adhesive.

For torn and bruised wound, antiseptic *per se* are valueless because they cannot reach all parts of the wound; they cannot penetrate the dead tissue into which infection is driven and all of them are to an extent devitalizing to the vascularized living tissue. Such a wound is treated by one packing of gauze soaked in sterile oil. The surrounding skin is then sterilized by a gauze scrubbing with a saturated solution of sodium bicarbonate, then a gauze wiping with 60 per cent alcohol and, finally, with ether. The sterile packing is then removed from the wound. All dead or partly dead structures are cut away with a sharp knife, since tissue torn and crushed to death is always surgically dirty and never comes to life. Hemostasis is made complete, and the raw vascular surfaces are placed in accurate apposition. Then stitches are applied, preferably buried, and no dead space left. If the wound cannot be closed without undue tension, partial closure is indicated, further operation being left for a later date. Stitches which shut off blood supply promote infection.

The wound should heal under one dressing. The dressing should be light, not more than four layers of gauze; small, just covering the wound; and held in place by narrow adhesive straps. The wound should be kept at rest, but circulation should be encouraged by movements or activities other than those which directly affect the relation of the wound surfaces of each other. The light dressing keeps the skin dry, allows ventilation and what is most important, permits prompt recognition of discharge which, when seen, calls for a change of dressing, this procedure always to be accomplished by using sterile instruments. A thick dressing keeps the discharge warm and moist in contact with a sweating skin, where it can do much harm.

Punctured wounds call for treatment in accordance with the nature and the amount of infection carried by the penetrating instrument. Needle and pin punctures, if the part be rested, are usually harmless. Puncture with dirty meat hooks, rusty nails, and other such injuries are also contused and lacerated, and, as they contain at their deepest part dead and infected tissues such wounds call for immediate opening to their deepest part, removal of ragged and torn muscle and fascia, with closure as for incised wounds. The injection of an antiseptic in the tract of such a wound is often times helpful to the surgeon.

Tetanus does not occur in wounds that are kept clean, as it requires for its development mixed infection and, usually, infection under tension. Tension means bloodless tissue, which means dead tissue, which means culture media for bacteria.

The results of the treatment outlined have been followed out in some twenty-four hundred cases, and there have been only three infections in the past year, two from hand infections and the third involving a foot. All three were because the men failed promptly to report to the dispensary for treatment.

Safety in Prompt Measures

Our rule requires a man even though his injury be a scratch to report at once to his foreman who sends him to the dispensary.

In the case of blisters, common forerunners of palmar abscess, we have found that infection can be obviated by puncturing, injecting Dichloramin-T through syringe or catheter and dressing.

In dispensary practice, where infection has occurred, always because of delayed or inadequate treatment, we have found the cure of abscesses to be hastened by two small incisions rather than by one large one, permitting through and through drainage and irrigation with 2 per cent Dichloramin-T once or twice per day. Drainage is left in for only a few days; the protecting dressings were light, and strapped on with adhesive.

In the spreading infection, the use of early surgery, consisting often of the anticipatory incision, is recommended; this to be followed by the application of heat, hypertonic solutions, and adequate splinting. From our experience two principles as to practice may be deducted: (1) The industrial surgeon will save his company annually many hundred times his salary by giving the employees prompt and adequate surgical service; and (2) where many infections occur among employees, it is certain that they are receiving neither prompt nor adequate surgical service.

*Read before the Fifth Annual Meeting of the American Association of Industrial Physicians and Surgeons, New Orleans, April 26-27, 1920.

THE EXPERIENCE OF THE MEDICAL DEPARTMENT AT NITRO, W. VA.*

By J. A. WATKINS, M.D., Medical Officer in Charge, Department of Industrial Medicine and Public Health, University of Cincinnati; Medical Director, Lunkenheimer Company, Cincinnati

THE results obtained in inoculating against typhoid fever were not so satisfactory as the measures employed for the prevention of smallpox. This phase of the work is of interest on account of the fact that the conditions at Nitro seemed to offer a favorable opportunity to test the measure on a large scale. The great difficulty in this instance was experienced because of the severity of the reaction and difficulty in having the patient return for second and third treatments. The first inoculation was rarely refused, but it was with great difficulty that these persons could be convinced of the desirability of returning for the second and third injection.

In the beginning triple bacterin, *i. e.*, typhoid paratyphoid "A," and paratyphoid "B," were used. Violent reactions were observed in some, and very severe reactions in practically all instances. After experimentation and inquiry into this subject it was thought that the paratyphoid "B" strain was probably the cause of the severe reaction. Paratyphoid "A" and "B" were discontinued and the straight typhoid bacterin used. This protective measure was inaugurated and pushed with a great deal of energy, starting early in March.

It is well that such precautions were taken for the Kanawha Valley, in which typhoid fever had been reported as endemic for a number of years, experienced an unusual prevalence of this disease during the summer of 1918. The unsafe condition of the milk supply was generally recognized, and the water supply of Charleston, near which city Nitro was located, was publicly condemned through newspaper notices by the State Board of Health. It is probable that the condemnation should have been also made of the water supply of several small suburbs in the neighborhood of Charleston and Nitro.

In addition to the exposure of Nitro employees and residents to this great source of infection, many thousands of whom visited these towns daily, many employees swam the Kanawha River, a stream grossly polluted by sewage, and in other ways exposed themselves to this disease in places without the control of the Nitro authorities. Preventive typhoid inoculation had been made practically compulsory at Nitro since the first week of March, several thousand persons having been so treated. Owing to the large labor turnover, however, many of these persons had left Nitro, while others arriving would thus be exposed in Charleston and environs to this infection before arrival at Nitro and before sufficient time had elapsed for them to receive the benefit of prophylactic treatment. A number of persons also arrived at Nitro ill with this disease, requiring to be taken from employment office to hospital.

The subject of typhoid fever received the careful attention of the medical department; the epidemiology of every case was traced in detail; complete data was available, and all precautions were taken. A total of 105 cases received medical attention from the medical department with a diagnosis of typhoid fever. Of these 105 cases it was possible to confirm the diagnosis by laboratory means in only fifty-one instances. The remaining

*The third installment of an article on the experience of the medical department at Nitro, W. Va., published in successive issues of Modern Medicine, beginning in April, 1920.

fifty-four cases exhibited obscure, slight fever from two to nine days duration, with some gastro-intestinal symptoms, and purely for precautionary reasons or a public health standpoint were diagnosed on clinical signs only, hospitalized, and cared for as typhoid fever. In view of the prevalence of gastro-intestinal complaints, it now seems probable that the 54 cases last mentioned should have been classified with these cases.

Of the 51 cases confirmed by laboratory diagnosis it was possible to trace the origin epidemiologically to the following places: 7 to Dunbar, W. Va.; 1 to Rockford, Ill.; 16 to Charleston, W. Va.; 4 to Chicago, Ill.; 3 to Lock 7, W. Va.; 1 to Boston, Mass.; 10 to St. Albans, Vt.; and 1 to St. Louis.

While two originated in either one of the following cities as the persons were taken sick within a few hours after their arrival at Nitro, and during the incubation period of the disease had been in one or several of the following cities: Cincinnati, Kansas City, Chicago, St. Louis, New York, or Washington. The origin of six was traced to Nitro. Three occurred in a private mess run by several civil engineers on the outskirts of the plant itself. Epidemiological study in these cases traced the source of the infections to a typhoid carrier who was employed in the commissary department of this mess. One case, a nurse, probably was infected at the bedside. It is very evident, therefore, that an enormous amount of infection was in the valley and that the most ideal conditions only could have hoped to have excluded typhoid fever from the employees of the plant.

Among the cases admitted and definitely diagnosed as typhoid fever were a number of cases which had received prophylactic treatment: 2 had completed triple vaccine prophylactic treatment in the United States Army five months before; while 10 had completed typhoid vaccine treatment at Nitro, having received one typhoid vaccine treatment in Charleston; 7 had received two injections only; while 26 had received one injection only during the probable incubation period of the disease. Among those who had completed prophylactic treatment and who later were infected with typhoid, were one doctor and one nurse. It should be stated here, however, that except in one instance the disease ran a very mild course and was of short duration in those who had received prophylactic treatment. Death occurred in the case of this person who was the wife of a Nitro employee. She had completed prophylactic treatment two weeks before onset, and had lived in Charleston until taken ill, when she was removed to Nitro and hospitalized. It would seem, therefore, that such acquired immunity is not protection against massive infection, nor is it probable that such immunity is well established for some time after the completion of the prophylactic treatment.

Of the employees of the plant 55,514 received one prophylactic treatment; 35,379 received two injections; while 25,793 completed the treatment.

In addition, such treatment was insisted upon in the case of dependents of employees before being certified as entitled to assignment to a bungalow. The manner in which the women and children reported for these protective measures was very gratifying. The children were inoculated on the basis of weight up to seventeen years, above which age adult dosage was given.

TYPHOID INOCULATION OF WOMEN AND CHILDREN

Age Group	Number Treated
Under 2 years	4
From 2- 6 years	232
From 7-11 years	159
From 12-16 years	133
From 17-45 years	2,282
Over 45 years	37
Total	2,847

Incidence of Influenza

This disease ranks highest among those diseases which existed in unusual prevalence at Nitro. As stated elsewhere in this report, the medical department had advance knowledge of the pandemic and had completely outlined the precautions to be taken at Nitro, and consistently carried these out, yet we were overwhelmed with this disease. The precautions that we took were in no way different from those instituted by many others, and need not be discussed here. It should be stated, however, that were the author to prepare for another epidemic of this disease, under the same circumstances as those that obtained at Nitro at that time, he is at a loss to know what changes could be made, or what additional precautions could be taken.

The first case of influenza arrived in the person of an executive returning from New York City. The case was properly cared for from a preventive standpoint. Two days later three cases arrived from New Jersey, which were also cared for, and within a few hours a train load of laborers from Pittsburgh, Pa., arrived with thirty or forty cases aboard, which were immediately placed in the hospital and the necessary precautions, as we understand the disease now, were taken. From this time on the medical department lost track of the epidemiology of the disease at Nitro. It appeared here and there, and with an ever increasing number of cases. Within a few days we had dismissed the idea of protection of

the population as a whole and confined our activities to the medical care of the individual solely.

Various phases of the epidemiology of this disease have been discussed in many publications, and the clinical and laboratory observations are more accurate and complete than those which were obtained at Nitro. Such data will, therefore, be omitted from this discussion. Some general figures, however, are pertinent to a discussion of the disease.

In all, 6,612 cases came to the attention of the medical department; 3,031 were hospitalized; and 211 cases died. The age group, 17 to 21, presented the highest case rate and case mortality rate. It should be noted, however, that the age group, 21 to 31, at Nitro was reduced because of the operation of the Draft Law. Of those dying from influenza or its complications the greatest number of deaths occurred on the fourth day.

Safety First Activities

The safety work was organized and directed by Mr. C. B. Hayward, M. E., formerly safety engineer for the Winchester Arms Company. This department prosecuted an intensive campaign for the prevention of injury and the results obtained were not only gratifying, but rather remarkable. There are given below condensed data compiled by this department. It is noteworthy that but 0.2 per cent of the number of working hours were lost by injuries resulting from accidents.

The rate of labor turnover in *per centum per annum* was 620. The severity rate of accidents in per day 1,000-300 day workers, showed an actual loss of 7.4 hours. The frequency rate of accidents per day per 1,000-300 day workers was 0.2 per cent, only two accidents. The accidents preventable by mechanical safeguards numbered 22, with the total fatalities numbering 12. Total accidents recorded are 10,697, of which 743 were lost time accidents, and 416 were compensation accidents. The actual lost time was 12,052 days.

Organization of Sanitation

The problems of sanitation presenting themselves in the work at Nitro, though they existed in large proportion, would not require a medical education and training of the responsible person. They were problems commonly presented and repeatedly and satisfactorily met by many engaged in such work during the past few years. A man with a good sanitary engineering education, with some practical experience, and possessing executive ability, is especially fitted to carry on this type of work. It appears from the Nitro experience that the work, which is the main routine and in reality lay sanitary policing, is for administrative purposes best carried on by other than the medical officers. It involves much detailed labor and time of purely executive character. Much money and labor are expended in the United States in removing garbage, cleaning streets, and the like, by public health organizations out of money appropriated for public health activity that does not, relatively, exert its share of influence on

A typical ward in the General Hospital at Nitro, W. Va.

the state of health of the population. That the work should be done under the general supervision of the health officer seems imperative, especially that of the operation of the water supply system. This plan, however, offers the one very undesirable condition of a divided authority. With proper cooperation divided authority can exist and conflict be avoided; otherwise dangerous possibilities are presented. This was experienced at Nitro. Ordinarily the health officer of a city has no hand in the detailed operation of the water works; he should, however, examine the public supply and point out any potential dangers. Critical action on his part should carry authority. At Nitro the best operating condition did not exist between those at the water works and the public health officer. To a great extent this was due to the extreme pressure of activities in connection with the construction job; partly to a misunderstanding, or rather to a lack of an understanding, and to a lesser degree to petty personal antagonism and conflict between subordinates of both departments.

A few cases of slight abdominal distress and diarrhea were brought to the attention of the medical department early in March. The cases were mild and of little importance; they presented, however, from time to time, until the week of July 1 to 7, when the cases appeared in epidemic proportions, no less than 1,610 cases coming to the attention of the medical department during this period. In an urban community where such detailed and full medical relief was not available few of these cases would have reached a physician. The Medical Officer in Charge, in order to bring the seriousness of the condition forcibly to the attention of the executives of the plant, requested the Surgeon General to detail Professor Phelps, of the Hygienic Laboratory, to make a survey and report on the water situtaion. There were only seven recognized cases of enteritis of sufficient severity to require hospital admission. There were no deaths and few remained in the hospital more than a day or two. Prof. E. B. Phelps and Passed Assistant Surgeon Neill, of the Public Health Service, visited Nitro and went into the matter at hand thoroughly. As a result of their investigation they came to the following main conclusions:

(1) Our investigations have not disclosed with any degree of definiteness the exact nature or cause of this outbreak.

(2) The polluted character of the Kanawha River, the chief source of water supply at Nitro, the overloaded condition and general inefficiency of the waterworks, and the relations between the rainfall stage on the one hand and the incidence of cases on the other, all indicate with a considerable degree of probability a causal relation between water supply and the outbreak.

(3) Investigation developed that certain special groups among whom a high case rate occurred, were furnished drinking water of good sanitary quality; furthermore, there was a disproportionate concentration of cases among those eating at one of the nine mess halls at the plant. These facts lead us to recognize the probability of contact infection as an important tributary cause of the outbreak.

(4) The relation between atmospheric temperature and the incidence of the disease rather strongly indicates that hot weather was an important contributing factor in the incidence and severity of the outbreak.

(5) A clinical study of the patients revealed no evidence to suggest that we were dealing with a severe form of dysentery, typhoid fever, or cholera; however, the epidemiological and clinical evidence indicates that these cases of enteritis were due to the entrance of the living micro parasite into the gastro-intestinal tract.

These gentlemen recommended that the permanent water plant be rushed to completion at the earliest practicable moment; that, pending this date, artesian well water rather than that obtained from the Kanawha River through the temporary water supply be used; the elimination of conditions which would decrease the possibility of contact infection, such as stringent personal cleanliness in kitchen employees, and other minor recommendations.

Most of the recommendations were placed in effect within a few hours, and the permanent water supply was placed in operation some time later. It would seem probable that we were dealing here with a mild type of water-born gastro-intestinal infection as described by Lumsden, Frost, and others. This form of enteritis, however, showed no tendency to decrease at a greater rate than it had for some time in the past. In addition, the same type of enteritis was reported as being unduly prevalent in all the surrounding territory, not only in urban communities up and down the river from Charleston to Cincinnati, but among farmers and those in rather isolated localities in the interior. The disease gradually disappeared, however, and by September no cases came to the attention of the medical department.

Sanitarians Should Control

The disease affected very little the non-effective rate, and demanded hospital admission in only a few instances. There were no deaths, and so far as we have been informed, no sequelae. The occurrence of this disease, however, emphasizes again the necessity of executive laymen concerned with the erection and operation of a water plant to be guided by the recommendation of the health officer and bacteriologist.

The plans for the permanent water supply called for the construction of a purification plant having a capacity of ninety million gallons of water a day. There was, of course, immediate

and urgent need of a safe water supply pending the construction of this plant, of such size that months of labor were necessarily involved. A temporary system, taking from the Kanawha River, was therefore placed in operation. This consisted of movable pump units at the river edge, alum-feed apparatus, chlorinating apparatus, vertical pressure filters with a combined area of 120 square feet and a tank storage capacity of one million gallons. This plant was poorly de-

Receiving room of the General Hospital. The booths on the right are men's dressing rooms.

signed in several ways. In addition, it proved to be inadequate and was several times enlarged. A source of great danger was the manual control of chlorination system, which, together with the type of employees available at Nitro, became a great source of danger. A few mains only were placed in operation. The failure to acquire and maintain an adequate and safe supply to meet the needs of a rapidly increasing population brought to mind alarming possibilities. The sanitary department was in this emergency directed to assume the responsibility of the distribution of water from known safe sources. Wood stave and steel tank wagons and large milk cans carried on wagon trucks, were placed in operation. Pending the acquisition of a safe public supply, this department performed an immense amount of work in a commendable manner, distributing no less than 2,600,000 gallons of water.

Sewage Disposal System

The plans for the permanent sewage disposal system were elaborate. They were, however, repeatedly altered. This and other factors brought about delay of construction which at times appeared serious. In unsewered areas the standard type of Army latrine was used. Seats were washed off each day, pit burned out, and the structure kept in good repair. They were, in general, satisfactory. The great area of the reservation and floating gangs of workmen necessitated many changes of location.

Dr. Otto P. Geier, of Cincinnati, visiting Nitro at this time, suggested that a type of housed sanitary privy, placed on wheels or skids, following the gangs from place to place on the plant, and capable of proper cleansing and attention would be more satisfactory. After our experience we believe this is much more satisfactory. One seat should be provided for every twenty-five men on duty. Six seat units proved to be the size best adapted for this kind of work.

Garbage and Refuse Disposal

Garbage and refuse were at first burned in an incinerator designed by Mr. R. D. Bates, the sanitary engineer in charge. Later, garbage was fed to hogs and an attempt made to salvage refuse. The latter was not altogether satisfactory, though no good reason for its omission under similar circumstances was observed. Lumber scraps were collected and used in such incineration.

The anti-mosquito work was simple. Mosquitoes were not unduly prevalent and so far as our collection shows there were no disease carriers. The work consisted in minor drainage and oiling operations.

The problem of fly control in respect to disposal of manure presented no new phases, but difficulty

The cadaver chamber in the mortuary building, Nitro, W. Va.

was experienced because of interference with rapid and adequate transportation and disposal due to poor roads, continued rains, and warm weather; also, inability to find farmers to take the manure as fertilizer. These obstacles were, however, overcome and the condition of the stables, housing thousands of animals, was at all times satisfactory. This was due to a great extent to the assistance and cooperation of the very progressive veterinary surgeon in charge of the animals. In the period covered by this report dis-

position was made of hundreds of thousands of tons of manure.

A system of food inspection was instituted which may appear to have been too elaborate, but under the particular construction and operating conditions at Nitro it was found to be not only of value, but necessary. Nitro was somewhat isolated, transportation facilities limited, storage and refrigerator space entirely inadequate, and housing for the preparation and serving of food in general provisional only. Mr. G. W. Taylor and six assistants conducted this work in a satisfactory manner. The quality and condition of food were carefully controlled from its source to the time of consumption. The conditions under which it was received, stored, handled, prepared, and served were under the continuous observation of an inspector. All employees concerned with this work were physically examined before being employed and inspected by a medical officer twice a month. They were inoculated against typhoid and vaccinated against small-pox. Of the several million meals served no case of food poisoning came under the observation of the medical department. The officials who handled the commissary cooperated with the sanitary department in every way.

Reconstructed Milk

The unsafe condition of the milk supply in the Kanawha Valley was generally recognized. In the emergency no time could be lost in correcting this as the conditions under which corrective measures must be instituted were not conducive to a rapid or satisfactory prosecution of the work. Upon recommendation of the medical officer in charge the executive officer of the plant authorized the erection of a plant and the purchase of materials necessary for the reconstruction of milk from milk powder and butter. Aside from the administrative duties of the operation of the plant, the responsibility was placed by the Surgeon General upon the Hygienic Laboratory, Washington, D. C. Prof. E. B. Phelps, chief of the Division of Chemistry, Public Health Service, assumed charge of this work, being assisted by Sanitary Chemist Stevenson, P.H.S., and Mr. George Peck, milk plant superintendent.

The operation of this plant was of immense benefit to the medical officer in charge in his endeavors to control communicable disease, in the control of sanitary matters pertaining to food stuffs, and in the feeding of hospital patients. The chemistry and all matters relating to the process cannot, of course, be discussed here, but will no doubt be made the subject of a special report in the near future by the Hygienic Laboratory.

(*To be continued*)

CHOOSING THE INDUSTRIAL NURSE

By R. T. SOLENSTEN, Assistant Secretary National Safety Council

THE experience of the many members of the National Safety Council who have attained a high degree of efficiency in their medical work indicates that employers who contemplate engaging the services of an industrial nurse should select one who combines the qualifications of "sick" nurse, "health" nurse, and social worker.

The industrial nurse should be a registered graduate nurse because she must be equipped by training to give first aid and to care for the minor ailments of employees under the supervision of the plant physician. The fact that a woman will not turn pale at the sight of a bleeding finger, or that she has a reputation for being handy in caring for sick people, does not qualify her to undertake the responsible duties of a nurse in an industrial plant. A partly trained woman in such a position is a potential source of danger because she is liable to overestimate her own ability and at a critical time misjudge the relative seriousness of accidents or illnesses. For effective work the industrial physician, whether employed on full time or part time, needs the expert assistance which can be supplied only by a nurse who is properly trained.

It is the function of an industrial medical department to prevent sickness among the workers as well as to treat injuries and attacks of illness. Therefore the nurse who is employed in this department must be a health nurse as well as first aid and sick nurse. She must be on the alert to prevent the introduction and spread of contagious diseases through the plant. She must be capable of teaching the workers how to keep well. She must be able to recognize physical deficiencies in employees which can be corrected or relieved so as to improve their health and efficiency. She must understand the general principles of sanitation, so that she can assist the physician to make inspections of the sanitary conditions in the plant and to see that suitable precautions are taken to protect the health of workers employed at dangerous trades or operations. To render service of this kind it is quite evident that training and experience in public health nursing are required.

But it is not enough that the industrial nurse be a capable sick nurse and health nurse. She should also have the qualities of the successful social worker. The first thing that the social worker learns is to render intelligent service in a friendly way. The second is cooperation.

The industrial nurse must at all times be a friend and co-worker of the employees. If she fails to win their respect, friendship, and confidence, she will not be successful. They will not readily follow her advice and instructions; they will not voluntarily seek her services when needed and her opportunities to do the best work will be lessened. . . . She must have the personality, poise, tact, and understanding of human nature which will enable her to cooperate with all departments in the plant, as well as with all public health agencies.

Employers who have experienced difficulty in obtaining a properly trained industrial nurse will do well to communicate with the National Organization for Public Health Nursing, 156 Fifth Ave., New York City. This organization is deeply interested in industrial nursing, and its officers will gladly assist members of the Council to obtain a capable industrial nurse. The Association maintains an informal employment bureau and is in touch with public health nurses and organizations for various forms of public health nursing throughout the country.—*National Safety Council.*

MEDICAL RED TAPE

ALL men who are hired by the Cincinnati Milling Machine Company are now physically examined. Those who do not fully appreciate the advantages of a physical examination before going to work will be interested in the following:

Occasionally an applicant for a new job will say, "Why all this red tape? This is the first time I was ever required to be examined before taking a new job. What's the idea of this?" When applicants say these things it gives the plant physician an excellent opportunity to explain the advantages of a physical examination. After the examination has been made the applicant readily sees and always admits that it is not red tape, but a good thing.

The Worker's Attitude

In actual practice it works out about like this. During the examination the physician will ask, "Were you ever examined before?" The answer usually is, "No, not for several years," or perhaps, "Never." Again another one will say, "No, but I know I am all right." If the applicant has been in the army or navy he is likely to say "Yes, I wish I had a dollar for every time I have been examined." The physician then explains that no one can know his condition unless he is carefully examined, and this no one knows better than the ex-service men.

Everyone is subject to many kinds of diseases—some you know about and some you do not. All diseases are more or less a detriment to yourself. Some are contagious and a detriment to others if they take the disease by contact with you.

When a man is asked if he would want to work alongside of someone with tuberculosis he invariably answers, "I should say not." "If you were working in the shop would you want the firm to hire a man with the smallpox?" You know what his answer to this question would be. "Would you want a man to work alongside of you who had scarlet fever, diphtheria, or syphilis, making it possible for you to contract the same disease and in turn give it to someone in your family at home?" By this time the man recognizes the advantages of an examination and says, "I see it's a good thing, after all," or more frequently, "It's a good thing for me and it also protects the men in the plant."

Work Properly Adapted

Besides preventing contagious diseases from getting into the shop physical examination has other advantages. A certain percentage of people are handicapped by physical defects which become more serious if they work at certain kinds of jobs. A man may have a rupture, for instance, and not know it. Such a man is advised to get a well fitting truss before going to work, especially if the job for which he is applying requires lifting. Another applicant may have heart trouble, but of such character that certain light work would be harmless, while other heavier work would further damage his heart condition. In such a case the employment manager is advised about the situation and is thus able to properly place the man in the shop. Another man may occasionally have attacks of asthma or bronchitis. He, too, must be fitted into the plant to his best advantage. Another on examination may prove to have poor eyesight. He is advised to see an eye specialist in order to get properly fitted glasses. He can then see better to do his work more efficiently and at the same time preserve his eyesight by relieving unnecessary strain.

Several men have recently been examined for positions and found to have serious physical defects, such as tuberculosis and Bright's disease. Such men are advised frankly of their condition and are told to seek their family physician for treatment. If they have no family doctor, they are given the names of some competent physicians or specialists for their particular illness. Such men are thus placed on the first step towards regaining their health and earning power.

Sole Object Is Protection

No man is examined in this plant for the purpose of keeping him out of a job. The object is solely to protect the men already in the shop and to protect the newcomer from doing work for which he is physically not fit.

How would you like to work under a craneway if the operator of the crane was subject to heart trouble or epilepsy? It would be rather uncomfortable for somebody if in one of these attacks he should suddenly lose control of the levers and drop a ton or so of castings among a group of workers. You would probably say, "That's some management."

Every man or woman should know his or her own physical condition. The danger lies in not knowing of the existence of serious physical defects. Such people should seek employment only under the advice of a physician. Men would probably prolong their lives five years on the average if they had a complete thorough physical examination once a year. Our medical department is here for such service. Use it.—*Employees' Service News, Cincinnati Milling Machine Company.*

UNFIT MEN COST MILLIONS

Mistakes in enlisting men unfit for the strain of military service will cost this year twelve million dollars, according to the statement of Col. W. C. Rucker, chief medical officer of the Bureau of War Risk Insurance, in a discussion of psychiatry before the recent meeting of the Association of Military Surgeons in New Orleans.

"The lack of sufficient care in examining men drafted is the cause of this great expense," said Colonel Rucker, "—care that is from the viewpoint of their mental make-up and history. The men should not be entered into the army until they have had a period of probation. Weak bodies usually mean weak nerves and it takes the best and strongest bodies and nerves for army service. I hope that in the future men will be excused from army service unless they are the kind best adapted to service as they prove an enormous drain on the country after war."

Colonel Rucker said there were 77,000 cases of neuropsychiatric disorders in the American army during the war, of which 11,000 were cases of insanity. "There are still 13,000 service men in our hospital," said the colonel, "40 per cent of whom are suffering from neuropsychiatric afflictions.

In four years from now the peak of the curve, it is expected, will be reached in neuropathatic cases, and it is estimated that, by this time, the government will have to spend $40,000,000 a year to take care of them."

ACCIDENTS COST $50,000,000 YEARLY

Of the 38,000,000 working men and women in the United States the Division of Safety Engineering finds that 700,000 annually lose limbs or are laid up by accident for an average of four weeks. The money loss in wages aggregates $50,000,000. Human carelessness is chiefly responsible, and in only 12 per cent of the cases are industrial accidents directly chargeable to machinery.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

THE RED CROSS AT GENEVA

IN one field of human activity, at least, the dreams of a saner and finer international organization of world affairs which we entertained a year ago are in process of actual realization. In the spring of 1919 Henry P. Davison, one of the really great figures of the war, began to plan the utilization of the social energies of the Red Cross societies of all nations for constructive peace time service. He interviewed statesmen, he convened the leading health authorities at Cannes for advice and counsel, and at last he organized the League of Red Cross Societies, representing the Red Cross in the leading allied and neutral nations and pledged to a program of which the objects are as follows:

(1) To encourage and promote in every country in the world the establishment and development of a duly authorized voluntary national Red Cross organization, *having as purposes the improvement of health, the prevention of disease and the mitigation of suffering throughout the world*, and to secure the cooperation of such organizations for these purposes.

(2) To promote the welfare of mankind by furnishing a medium for bringing within the reach of all the peoples the benefits to be derived from present known facts and new contributions to science and medical knowledge and their application.

(3) To furnish a medium for coordinating relief work in case of great national or international calamities.

There are two particularly notable things about this action. In the first place, it involves a very definite change and a very definite enlargement in the program of the Red Cross. Established to relieve the sufferings incident to war, the Red Cross societies have long devoted their energies to the relief of distress caused by sudden emergencies, such as floods and conflagrations. The step from such remedial measures to a constructive preventive program is a long one, but it is a step wholly in line with wise and modern policy in every line of endeavor. It is better to build a fence at the top of the cliff than to erect a hospital at its base to care for the wounded after they fall over

In the second place, it is inspiring to note the speed with which this conception has been translated into action. The League of Red Cross Societies has been actually organized at Geneva and the first batch of publications detailing its plans have already been issued. Dr. Richard P. Strong, director of the General Medical Department of the League, presents a comprehensive outline of a bureau which includes divisions of bacteriology and epidemiology, sanitary engineering and vital statistics, research and publication, child welfare and tuberculosis, public health nursing and industrial hygiene; and all but two or three of these divisions are already organized and functioning. Among the Americans who are responsible for important phases of the work are Prof. G. C. Whipple, Sanitation; Dr. Thomas R. Brown, Medical Information; Col. H. A. Shaw, Communicable Diseases; Miss Alice Fitzgerald, Nursing; and Dr. S. B. Wolbach, Laboratory.

The new organization at Geneva is essentially a Health Department for the World, a bureau which should be in a position to offer counsel and inspiration to national health agencies, particularly in the more backward nations, exactly as our Federal Public Health Service advises and stimulates state health departments in this country. There are those who doubt the ability of the Red Cross to hold its clientele in peace times; but with this magnificent program we can hardly question that the needed support will be secured and maintained.

THE HEALTH DEPARTMENT AND THE HOSPITAL

ONE of the most complex problems of administration is that which involves the relation between the health department and allied agencies of government. In the past the extent to which health officers should be responsible for engineering functions—such as plumbing inspection, garbage disposal, and the collection of refuse—has been frequently debated, and authorities are agreed that the assumption of responsibility along such lines is to be avoided as far as may be possible in the individual case.

Today a new set of problems covering the interrelationships between the health department and the hospital are pressing for solution. Tuberculosis hospitals are developing dispensaries and sending physicians and nurses out into the community for consulting service and follow-up work. Hospitals for mental disease are expanding along similar lines. General hospitals, through their dispensaries and medical social service, are extending their influence far beyond the hospital walls. On the other hand, the health official who is alert and responsive to modern tendencies realizes more and more fully that the provision of adequate medical and nursing service for the community is one of the most essential features of the modern public health campaign. The far sighted and statesmanlike law presented to the New York Legislature, reviewed in Modern Medicine for April,[1] is a notable example of the tendency to develop such facilities as a part of the official health program.

1. This bill failed of passage in the last chaotic days of the session at Albany, but it will be brought up again early in the next session of the Legislature.

It seems probable that in the ultimate future the hospital and medical and nursing services of the community will to a large extent be centered in the health department. As Sir Arthur Newsholme has so forcibly pointed out, anything which tends to separate public health from curative medicine is detrimental to the development of both. Progress will, however, be gradual along this line,—and should be gradual, for the administrative task imposed on a health official responsible for such a wide range of service will be a staggering one. Meanwhile, we must recognize on the one hand that health work in the homes of the people belongs logically to the health department; and yet that interference with the extramural work of the hospital would work great harm in many instances. The patient before he enters the hospital, and after he leaves the hospital, is the same patient who occupies a bed while he is within its wards; and the hospital has, or should have, the expert service to reach out and find him while his disease is curable and to follow him up to see that his cure is complete. The illogical situations which must be dealt with for the present call for a maximum of patient and broadminded cooperation alike on the part of hospital administrators and public health officials.

EDITOR.

CHILD WELFARE IN KANSAS

THE women of Kansas have taken it upon themselves to bring into the laws and life of Kansas at the earliest possible date the minimum standards of child welfare as formulated by the International Conference on Child Welfare held in Washington in May, 1919. The ambitious program is worthy of the best efforts of any state, and the women of Kansas are to be congratulated on this step of far reaching importance to their state and Nation.

The first important activity of the State Committee is to make a state wide survey to discover the present conditions in Kansas with reference to the various interests of children as outlined in the international minimum standards. The survey is an attempt to uncover the actual community conditions affecting children in industry; the health of mothers and children; dependent, defective, and delinquent children; and other general interests of children.

The machinery for making the survey is very similar to that of the war-time fund raising organizations, with state, district, county and local chairmen down to the ward canvasser. In order to avoid criticism, the survey will be strictly impersonal and no names or personal data are to appear in any of the written material handled.

Among the more immediate effects expected from the survey are the following: (1) When the survey is completed and the results tabulated, the finished report will be turned over to the Children's Code Commission about to be appointed by the Governor. This should be helpful in pointing the way to needed legislation. (2) While the survey is in progress the State Committee will be working out types of community programs to fit the various community needs as they are uncovered by the local survey. Each community will be urged to follow up the survey by promptly attending to its greatest need. (3) While these communities are carrying out their various follow up activities, the fall elections will inject some new issues in local and state politics, and those candidates elected who will pledge themselves to a platform of children's rights. (4) When the Children's Code Commission submits its report to the legislature, the entire survey organization can be used as a gigantic legislative committee to insure the enactment of a constructive legislative program.

The Kansas Women's Committee on Child Welfare has a supreme task before it and, representing as it does the united effort of the women of the state, far reaching and permanent benefits are to be expected.

JULES SCHEVITZ.

1. Bulletin Kansas State Board of Health, February, 1920.

MENTAL HYGIENE AND PUBLIC HEALTH

AS long as insanity was considered a thing apart from medicine the religious and superstitious interpretation of this disease held sway. With the development of the scientific conception of the nature of insanity, the neglect of mental disease in the past has gradually given way to modern methods of treatment and prevention. A system of non-restraint and humane treatment has been substituted for blows and punishment.

That mental disease is one of the important health problems facing this country today is the testimony of Dr. William B. Terhune,[2] medical director, Connecticut Society for Mental Hygiene. "The prophylaxis of mental disease and defect," states Dr. Terhune, "is only one of the public health problems confronting us today, but it is a subject of major importance. . . . On January 1, 1918, there were 239,820 insane patients in hospitals, and 15,863 on parole. This represents 229.6 per 100,000 population. . . . There is no public provision in the United States for the care of psychoneurotics. Therefore they are not included in the above figures. Likewise, we cannot be sure as to the number of insane and mental defectives outside of hospitals." In 1917 an expenditure of nearly forty-four million dollars was made in this county for the maintenance of institutions for the insane.

The examination of the drafted men between the ages of twenty-one and thirty-one further revealed the startling extent of mental defects. Seventy thousand inducted men were found unfit for military service because of nervous and mental disease.

It is estimated that one-third of insanity and three-fourths of feeblemindedness can be prevented, and, considering the disastrous health and social consequences of these mental ailments, the public health significance of this problem is readily apparent.

Alcohol has been found to be a contributory cause of insanity in about 8 per cent of the cases committed to institutions. Prohibition is already making itself felt by reducing this factor to a minimum. About 15 per cent of insanity is the result of syphilis, indicating a very distinct relationship between public health and mental hygiene. In urging the prophylaxis of syphilitic mental disease the author well remarks: "It is time that, as students of public health, we cease to lay the emphasis upon the venereal nature of syphilis which, after all, is its least important part, and put the emphasis where it belongs—upon the fact that it is a contagious disease."

The attack on the problem of feeblemindedness must be planned upon somewhat different lines. Since feeblemindedness is considered the result of a permanent abnormal brain condition and, therefore, incurable, the one effectual way to diminish the number of the feebleminded in future generations is to prevent the birth of those who would transmit feeblemindedness to their descendants. This is a clear example of a biological public health problem.

THE ARGUMENT FOR A BROADER ATTACK ON THE TUBERCULOSIS PROBLEM

By JOSEPH HERZSTEIN, M.S., Executive Secretary, Rensselaer County Tuberculosis Committee of the State Charities Aid Association, Troy, N. Y.

MORE and more anti-tuberculosis workers are coming to believe that progress in preventive activity demands increased attention to raising bodily resistance and promoting general health.

This is due to the peculiar nature of the tuberculosis problem. The great prevalence of the disease and the ease with which the causative agent leaves the body have resulted in a practically universal distribution of the tubercle bacillus. On this account there are not only innumerable persons with latent infection, but there are also abundant opportunities for "well" persons to receive reinfection. The change from a condition of latent infection to disease may be due to reinfection from without or to a failure of the bodily resistance which permits foci of infection to flare up. For a consummated attack on the disease it would appear, therefore, that not only must conditions for receiving the infection be reduced to a minimum but, in addition, equal attention must be given to measures for maintaining vital resistance at a high level.

A TRUE STATE OF WELL BEING

Health activities may be regarded as having one of two objectives—either freedom from disease or resistance to its ravages.

Sanitary measures are effectual as far as they go, but the immunity conferred by repeated onslaughts of disease is not a safe general measure, and the margin of safety from acquired immunity is a variable quantity.

An effective tuberculosis program is a general health program that turns to practical account all the scientific knowledge now available in the maintenance of a high level and the development of a high degree of bodily resistance.

This can be accomplished in part through the handling of other public health problems, many of which are intimately related to tuberculosis. It is the purpose of this article to indicate some of the health problems in which activity can be favorably pursued.

Before describing the points of contact of tuberculosis with other health problems, a brief statement of the existing tuberculosis situation seems warranted. The last report of the United States Census Department (1917) gives a total of 97,047 deaths in the Registration Area, due to pulmonary tuberculosis. The general estimate of morbidity from tuberculosis varies. About ten active living cases are said to exist for each annual death. At this rate there would be constantly about 1,000,000 active living cases of the disease. This would mean that one in every hundred persons in the United States is a possible source of infection with tuberculosis bacilli. Since one person may be a source of infection for months or years, the wide-spread existence of tuberculosis infection can be reasonably well accounted for.

According to Smith[1], about 90 per cent of white children between the ages of twelve and thirteen and practically all adults show manifestations of positive tuberculous infection, as indicated by the tuberculin reaction. Krause[2] states that about three-fourths of the children up to fifteen years of age show evidences of tuberculous infection.

We are led by medical opinion to believe that this early infection is the one which later in life manifests itself in tuberculous disease, when the disease finally makes its appearance clinically. This is plausible since the living bacilli of tuberculosis can be harbored in the healthy body over a period of many years. In this regard the immunity reaction of the body to invasion of tuberculosis bacilli is different from the reaction toward other pathogenic organisms. The actual life in the body of other pathogenic bacteria which fail to become toxic or numerous enough to produce disease, is very much more transient. In tuberculous infection the situation is different, the bacilli remaining dormant but viable. As Krause suggests, the avoidance of tuberculosis involves keeping the body in a condition which will hold the already contained seeds of tuberculosis rigidly localized and inactive.

It becomes apparent, therefore, that strenuous efforts must be made to insure a sound resistance so as to stave off the development of tuberculosis. With a better control of general health the maintenance of a higher general vital resistance would be possible. Some of the factors in a better

1. Smith, F. C.: Tuberculosis, Its Predisposing Causes. Supplement No. 3, to the Public Health Reports, United States Public Health Service, Washington, D. C., 1919.

2. Krause, Allen K.: Essays on Tuberculosis. Jour. of Outdoor Life, February, 1919.

health control will now be discussed as well as the points of contact of the tuberculosis problem with other health problems.

Infant Welfare Work

In the earliest years of life there exists a serious condition which is destructive not only of vital resistance, but also of life itself. A study of the New York Milk Committee[3] for the years 1906 to 1911 in Chicago, Philadelphia, St. Louis, Boston, New York, and other large communities showed that of all the deaths in each of these cities, about one-fifth took place in children less than a year old. The occurrence of so many deaths is indicative of a tremendous amount of sickness which does not culminate in death. Is it not plain that here the first blows upon vital resistance are dealt?

Although the regenerative powers of the body are very remarkable, it is often the case that an organ recovers with some morphological or functional defect after passing through a pathological condition. Whooping-cough, for example, is capable of producing more or less permanent harm to the lungs. Early disease can undoubtedly handicap a child in its later growth.

The main causes of infant mortality are (1) congenital defects, (2) digestive diseases, and (3) respiratory diseases. Respiratory diseases alone killed more than 27,000 children under one year of age in this country in 1917. Similar numbers were lost in previous years. The number of children who pass through non-fatal sieges of pneumonia and bronchitis is many times that amount. The methods of prevention of these diseases are known. Instruction to mothers in regard to the care of the baby—its feeding, clothing, bathing, and sleeping conditions—would undoubtedly reduce the amount of sickness which lowers bodily vitality.

How many of these children will be on the tuberculosis morbidity list later? We need to do more to prevent infant mortality and morbidity. Any community can reduce its infant mortality and morbidity by using knowledge already available and practices already successfully tried.

Measures for Milk Sanitation

The problem of infant welfare work is indissolubly connected with that of control of milk supply and sanitation. Milk is a food which occupies a position of supreme importance in nutrition. It is one of the "protective" foods necessary for bodily growth. Milk is often so liable to carry disease producing bacteria that it requires almost as much attention as the control of a city water supply. The milk problem has a far larger health significance than people are usually aware of.

Dirty milk has played tremendous havoc with human life. Dublin[4], in a careful statistical study of mortality of childhood in the United States for the years 1910-1915, finds that 24.4 per cent of all the deaths in the first year of life are due to enteritis and diarrhea. In the second year of life, these maladies are the principal causes of death, the percentage due to them being 27.3 per cent. Much of this sort of illness is undoubtedly traceable to bad milk.

The tender gastro-intestinal membranes of infants may be overwhelmed by a mass attack of an abundance of bacteria. The process of pasteurization can very effectively reduce this danger from milk. When the use of pasteurized milk was extended in New York City, a lowering of the death rate occurred, as pointed out by Eager[5]. After the number of bottles of pasteurized milk dispensed by Nathan Strauss had increased from 34,400 in 1893 to 3,000,000 bottles in 1906, the summer death rate among children under five years fell to 62.7 per thousand. Prior to 1893, the death rate was double this.

Milk may also be a spreading agent of other communicable diseases, such as typhoid fever, paratyphoid, dysentery, diphtheria, scarlet fever, tuberculosis, and septic sore throat.

Referring to tuberculosis, it should be mentioned that tuberculin testing of cattle has revealed the widespread existence of bovine tuberculosis. The results of state and Federal tests in forty-five states in the United States from 1893 to 1903 on 400,000 cattle, showed 9.25 per cent to be reactors. Schroeder[6] estimates that 20 per cent of the dairy cattle in the United States are infected.

Bacilli of tuberculosis in milk have been found by more than a score of workers. Hess[7] in New York City, found tubercle bacilli in 16.2 per cent of 105 milk samples. The literature shows that about 13 per cent of all samples analyzed contain bovine tubercle bacilli. Dr. Lawrason Brown[8] states it is estimated that 8 per cent of the deaths in the United States from tuberculosis are among children succumbing to bovine tuberculosis.

Milk infected with bovine bacilli is undoubtedly the cause of much bone and joint tuberculosis.

8. Brown, Lawrason: Rules for Recovery from Pulmonary Tuberculosis. Lea & Febiger, Phila., 1919, p. 8.

Park and Krumwiede[9] found among 171 children under sixteen who had tuberculosis that 20 per cent was due to the bovine bacillus. A study of all investigations on this subject by Wang[10] shows that one-third of the cases of tuberculosis in children under five years is due to the bacilli of bovine tuberculosis.

Hundreds of epidemics of disease have been traced to infected milk as the source. So far as records show, no epidemics have been traced to properly pasteurized milk supplies. Distinct progress in the prevention of unnecessary disease can be made through safeguarding community milk supplies. Education of the consumer about milk and its dangers is essential. This education must be carried to the farmer as well, and to those officials who by proper ordinances can help control the milk supply. The persons closest to the production problem often know least about the sanitary aspect of it.

If a clean, safe milk supply is to exist it must be obtained from clean, healthy cows milked in a sanitary manner. It must also be handled in sterile containers, protected from infection, properly iced, and kept cold until ready for use.

General Control of Communicable Disease

The terms "diseases of childhood" and "children's diseases" have almost become classic. It is common knowledge that innumerable children needlessly go through attacks of measles, scarlet fever, diphtheria, and other diseases. In New York City alone, from the years 1914 to 1918, more than 70,000 cases of diphtheria were reported. Twice this number of cases of measles were reported during the same period. Persons are often affected whose vitality can least afford to suffer an attack of disease. Do not such attacks tend to the presentation of more tuberculous material?

If these diseases are to be further controlled, health workers should agitate for better reporting by physicians, establishment of better public diagnostic laboratory facilities, health officers who enforce quarantine, more school medical inspectors, more school and public health nurses. Popular education about these diseases is very much needed.

Importance School Hygiene

How does the occupation of being a school child affect health? It is well known that the physical environment of school and the nature of school life play an important part in the lives of young persons. How many times have we entered schoolrooms and found them either overheated or mal-odorous? One has but to stop at a school during a period of dismissal to see pale-faced or unnaturally flushed children emerge from their classrooms. There is no measure, whatever, of the mischievous part poor schoolroom ventilation plays in lowering childhood vitality. School ventilation is a health problem which still requires much attention.

Of course the large number of defects discoverable among school children are not to be laid to the door of school life. Before children come to school, many have curable defects which, if neglected, continue to retard their healthfulness during the school age. In Cincinnati, examinations reported by Roberts[11] for the Social Unit Organization showed that among 640 children between the ages of two and six, there were 1,915 defects.

If a healthier youth is to be developed in the schools, it is essential that systematic physical examinations with proper records and effective follow-up work be conducted everywhere. It has been said that out of twenty million school children enrolled, 70 per cent manifest defects which are more or less in the nature of a handicap.

Dr. Thomas D. Wood* has emphasized the special need for health work in the rural schools. He states that more than half the school children in the United States attend rural schools. From a study of over a half million records of examinations he deduces a table from which some of the data are given below.

	Per Cent of School Children with Defects Noted	
Defects Noted	*Rural Schools*	*City Schools*
Teeth	48.8	38.14
Tonsils	28.14	16.42
Adenoids	23.4	12.50
Eyes	21.0	13.50
Malnutrition	16.6	7.65
Enlarged glands	6.4	2.70

With dental caries, enlarged tonsils, and mouth breathing, so common among school children, can we expect a very effective vital resistance? How many of the present million tuberculous persons have had their physical resistance retarded during their school life by neglected defects of this kind?

Space does not permit going into other details of school hygiene, such as school lunches, open-air schools for all children, and drinking water sanitation. Tuberculosis workers will do well to exert strenuous efforts to the end that the little

rural schools on the byways are visited by competent nurses, and that school medical inspection is always accompanied by school nursing.

The motto, "What profiteth it a child that he should gain the whole curriculum and lose his health?" should be one of the first to be taught to all engaged in educational work.

Industrial Hygiene

About one-third of the nation's people are wage earners. These persons work under industrial conditions which undoubtedly have an effect on health, since about a third of each day's time, week in and week out, is spent under special conditions of work.

A cross-section of the health equipment which most of the young males in this group possessed was obtained in the draft examinations, if it is correct to assume that a major portion of the men examined came from the wage-earning class. More than half a million men, according to the report of Provost Marshall General Crowder, were refused admission to the army because of health defects. Of the entire number examined, 30 per cent were unfit for full military duty.

Taking the industrial group as a whole, we find facts which indicate that conditions of industry are often very inimical to health. Dr. Dublin of the Metropolitan Life Insurance Company, states that out of 635,449 deaths in their industrial mortality experience from 1911 to 1916, 17.4 per cent were due to tuberculosis. He states that tuberculosis is clearly the chief burden upon the vital resources of wage earners and their families.

In a study of mortality in the dusty trades, and a great many are needlessly so, Hoffman of the Prudential Insurance Company found that between the ages of twenty-five to forty-four the percentage of deaths due to tuberculosis of the lungs and respiratory diseases was a follows:

Occupations Exposing to	*Per cent of Deaths*
Mineral Dust	41.1
Metallic Dust	45.2
Vegetable Fiber Dust	49.5
Animal and Mixed Fiber Dust	49.7

The figures show that about half of the deaths in the dusty trades are due to respiratory disease alone.

That industrial conditions of factory life can bring out hitherto latent infection was shown in the English experience during the war. It was noted that an increase in tuberculosis occurred among young girls who became wage earners.

If employment conditions as such are so harmful to health as to permit latent infection speedily to gain the upper hand, effort must be made to improve conditions wherever possible. More attention to medical examination of employees, plant ventilation, humidity, temperature, fumes, dust, fatigue, and other numerous factors of importance in industrial sanitation will have a beneficial effect on the tuberculosis problem.

Water Supply and Sewage Disposal

Impure water supplies and unsafe methods of sewage disposal play a dominant part in the causation of typhoid fever and other intestinal diseases which clearly undermine resistance. About ten thousand deaths from typhoid fever occurred in the United States Registration Area in 1917. Probably ten times this number were sick with the disease during the same period, the fatality rate of typhoid being 10 per cent, or one death out of every ten cases. In the community which takes its water from polluted sources without subsequent purification, or from wells receiving surface drainage, we expect and do find typhoid. The same is true where sewage is improperly disposed of, as in unsafe privies which are open to flies.

With so many persons subjected yearly to a long continued siege of exhausting illness like typhoid it is evident that bodily resistance may be quite seriously impaired.

Where attention has been paid to the proper sanitation of water and to sewage disposal, not only has the amount of typhoid fever decreased but tuberculosis and other disease rates have declined. This has been shown in an observation described among sanitarians as the Mill-Reincke phenomenon. Efficient control of these sanitary problems has therefore a far reaching effect.

Conclusion

The various health problems mentioned above as affecting vital resistance, and therefore also tuberculosis, do not by any means exhaust the number. It is felt, however, that those pointed out are sufficient clearly to indicate the soundness of the argument that the healthfulness of those not on the tuberculosis lists must be maintained at the highest level through proper health administration and education. Detection of the disease in its early stages is important, but no program can uncover all latent cases, and immunity is to be accomplished only through the development of a high degree of bodily resistance.

In the future, tuberculosis workers may profitably and legitimately give increased attention to such allied problems as infant welfare work, milk sanitation, communicable disease control, school hygiene, industrial sanitation, community water period, the fatality rate of typhoid being 10 supply, sewage disposal problems, and to health education in general.

TROPICAL DISEASES—COLLECTIVE ABSTRACT

By GEORGE L HOFFMANN, Ph.D., Chief, Division of Bacteriology and Serology, Research Laboratory, Western Pennsylvania Hospital, Pittsburgh, Pa.

UPON casual consideration the average physician pays little or no attention to tropical diseases here in the States. This attitude must not be attributed to indifference or lack of knowledge of the subject but rather to the lack of personal contact of the physician with these pathological conditions, which are somewhat in the minority as regards general incidence but which are nevertheless of more importance than is primarily imagined.

Medically, in the past, we have been a somewhat provincial nation. This has been the natural result of our diminutive merchant marine and tropical possessions. The recent war has done much to develop an interest in tropical medicine and has forced a great many of us to work in previously unacquainted fields. This condition not only applies to the United States but includes all the countries involved in the recent struggle. It might be presumed that tropical medicine would suffer greatly as a result of the decreased activity on the part of many countries in their tropical possessions and temporary inactivity of some of the tropical disease hospitals and laboratories, which were being maintained in domestic ports, these being immediately converted into hospitals and laboratories engaged in war work. Despite this condition, however, as a result of the magnitude and scope of the military operations, the medical men were immediately brought in contact with pathological conditions other than those which they had been accustomed to treating at home. Dysentery, cholera, plague, typhus, and Malta fever, which had previously been known by literary contact alone, were now actual conditions. Malaria was soon more than the administration of quinin t.i.d.

Today we find ourselves at the beginning of a cosmopolitan epoch of tropical medicine. At least, we must have a better knowledge of tropical medicine and those of us who have previously limited our practice to the diseases of the moderate climates must become cognizant of the tropical diseases, for they are gradually coming under our observation and are a developing condition which must be properly diagnosed and treated.

Malaria

The therapeusis of malaria has been entirely revised after passing through a most thorough stage of experimentation. Nothing new therapeutically has been established but there has been a new assemblage of previously confirmed facts, and these with the best proven prophylactic and general sanitation measures have culminated into a more or less routine procedure which is most efficient.

The importance of screening and other anti-mosquito measures need not be discussed. Bass[1] has most convincingly pointed out that in some communities from 50 to 70 per cent of malaria cases are relapses and not new infections; thus the importance of the sterilization of plasmodium carriers in malaria treatment can be readily seen.

Ross and James[2] have formulated suggestions for the care of malaria patients that are well worth observing. They emphasize the importance of a correct diagnosis and lay special stress on the close resemblance of malaria to pulmonary tuberculosis, liver abscess, and enteric fever, and call the attention of the diagnostician to the type of malaria in which the daily febrile paroxysm comes on before midday, a clinical sign which renders a diagnosis of malaria moderately certain.

In a foot note to the section on treatment they mention that the taste of quinin is quickly removed by masticating a piece of bread, and also insist upon the necessity for rest in bed at the commencement of treatment with quinin. Oral administration of the drug is recommended as a routine procedure. However, the indication and technic both for intravenous and intramuscular injections are given. Subcutaneous injection is not encouraged to the slightest degree.

In the remarks in "After-treatment," the following procedure is suggested:

(a) 10 grains of quinin once daily at dinnertime or at bedtime; or

(b) 30 grains of quinin on each of two consecutive days, *e.g.*, Saturday and Sunday of each week; or

(c) 30 grains of quinin every Sunday, the amount being taken in three doses of 10 grains each, the first in the early morning, the second at midday and the third in the evening; or

(d) 30 grains of quinin taken as in (c) but every tenth day instead of every Sunday.

The authors state that the choice of procedure is usually governed by the circumstances and character of the individual case, the procedure being selected which the clinician believes will be most conscientiously followed. If relapse occurs or malaria parasites are found in the pa-

2. Ross and James: Suggestions for the Care of Malaria Patients. H. M. Stationery Office, London, 1919.

tient's blood he is again put to bed and treated as if his attack were a new infection.

Stephens, Yorke, Blacklock, Macfie, Cooper and Carter[3] in a series of studies on the therapy of malaria have been unable so far to improve upon quinin therapy though several therapeutic agents, including organic preparations, have been tried. Despite the favorable reports of Patrick[4] on the intravenous injections of quinin and antimony, the use of the latter is still considered in the experimental stage only. So far little, if any, evidence has been produced which would further the encouragement of the use of intravenous injections of antimony preparations in cases of malaria. Patrick administered the quinin intravenously, using a 5 per cent solution of the bihydrochlorid in distilled water to which has been added 0.8 per cent of sodium chlorid. He usually gave three injections of 15 grains each on eight successive days. This was then followed by 6 grains daily by mouth according to the indications. Lowenstein[5] also reported most favorable results by the intravenous use of quinin salts after extensive experiments. He, however, used the hydrochlorid of quinin dissolved in distilled water at body temperature calling attention to the fact that this quinin salt was precipitated in physiological salt solution.

Miller,[6] Neumann,[7] and Lowenstein[5] speak unfavorably of the intravenous use of salvarsan or neosalvarsan in malarial infections. They have found no results warranting its use in any of the types of malaria.

Yellow Fever

The brillant researches of Noguchi[8] have taken yellow fever out of the chapter devoted to fevers of unknown origin. The detailed articles covering his investigations on the etiology of yellow fever that he performed in Guayaquil show that in a very thorough and convincing manner he has made a most valuable contribution to medical science. Noguchi has practically fulfilled Koch's postulates as regards his leptospira icteroides and its rôle in yellow fever. There seems to be little doubt that he has made himself master of this pathological condition and there only remains to be made, if need be, a confirmation of his researches by other laboratories. Noguchi has not stopped his researches with the isolation and study of the biological properties of leptospira icteroides but is continuing his work on the acquiring of immunity against such infections which proved so promising in the laboratory. These experiments are being carried out in southern Mexico. It is apparently only a question of time until the chapters devoted to yellow fever will be completely rewritten as regards etiology and treatment, then to be complete, concrete, and definite in nature and not, only complete as regards prophylaxis.

Arce[9] in a review of Noguchi's work points out the value of his findings and their importance, especially from a diagnostic standpoint, in countries where the benign cases of yellow fever in the child or adult are so difficult to diagnose, often passing unnoticed or being confused with other pyrexias so that they may escape the prophylactic measures aimed at the extinction of the fever.

Amebiasis and Dysentery

Despite the fact that amebic dysentery has usually been considered a tropical disease we are constantly meeting these infections in increasing numbers in daily practice. Kofoid, Kornhauser, and Swezy[10] have published a comparative incidence of the various amebae found in American troops and have found the following to be the average in 1,200 men examined. Entameba nana 28 per cent, E. coli 23 per cent, E. histolytica 9.3 per cent. Owing to the wide geographical distribution of E. nana, they point out the necessity of the examiner being able to distinguish E. nana from E. coli and the other amebae. Mixed infections of E. nana and E. histolytica are apparently very common.

The presence of highly refractive bacteria-filled food vacuoles in E. nana is of great value in differentiation. The authors have confirmed Wenyon in his statement as regards the absolute diagnostic criterion of the appearance of the structure of the nucleus in the stained specimen. In E. histolytica there is a central karyosome, the peripheral chromatin being scattered over the nuclear membrane in minute granules, whereas E. nana is devoid of a central granule and the peripheral chromatin is massed in a single large clump at only one point in the nuclear membrane. This contrast may sometimes be made in the living specimen. However, it is best made by using Donaldson's[11] iodin-eosin stain for the differential diagnosis of the cystic stage. The preparation is made by triturating a small portion of the feces in normal saline and gradually adding the following staining mixtures:

	Parts
Saturated solution of eosin in normal saline	2
Five per cent potassium iodide in normal saline saturated with iodin	1
Normal salt solution	2

The nuclei of E. coli and E. histolytica become clearer more quickly as the iodin penetrates than in E. nana.

Fischer[12] after careful investigations of the blood picture in amebic dysentery concludes that there is no typical change of the blood picture in cases of amebic dysentery even during the course of the disease. Matthews and Smith[13] have contributed a very important paper regarding the spread and incidence of intestinal protozoal infections in children. They found children to be infected from the second year upward and the infection to be equally common in both sexes. Of 548 children examined, all under the age of twelve years, 31.5 per cent were found to be infected with intestinal protozoa.

MacAdam[14] reports sixty-two cases of E. histolytica infection out of eighty cured by administering emetin hydrochlorid in the following manner: A total amount of 18 grains was given during a period of twelve days, administering each day 1 grain hypodermically and ½ grain orally. Following the treatment the stools were examined at regular intervals to serve as controls. Primary acute attacks and cyst-carrier cases were treated in the above manner.

Most of the work relating to bacillar dysentery has been along clinical and bacteriological lines. The question of the classification of the dysentery bacilli still apparently remains an academic one, for each worker seems to present some new group or biological feature which prevents the formation of specific group characteristics by either agglutination or classical sugar fermentation reaction.

Goldzieher[15] considers that for all practical purposes there need be but two groupings. (1) the toxic Shiga-Kruse group, and (2) the atoxic Flexner-Strong-Hiss group, making the fact of their biological difference (toxin, indol, and acid production), of their differing immune body content, pathogenicity, and clinical aspect, as well as their application to serum therapy. He also contends that the agglutination reaction is so unreliable that it is of little diagnostic value in cases of dysentery or for the differentiation of the organism into their respective groups. The statement is also made that the repeated administration of dysentery vaccines used therapeutically does not produce a rise in the agglutination titer of the patient's sera.

Yandel[16] believes that he has a specific remedy for the bacillary dysentery by administering (1) adrenalin chlorid hypodermically for the stoppage of hemorrhages, and, (2) thymol in large doses on an empty stomach as an alimentary antiseptic. He comes to this conclusion after his experience with an epidemic of 102 cases of dysentery at Sacaton, Ariz. Unfortunately, no mention is made of the bacteriological nature of the infection.

Dudgen considers the fly as the carrier of bacillary dysentery, giving the following reasons, "(1) Bacillary dysentery is most prevalent when flies are most numerous. (2) Flies, after infection with dysentery bacilli, are capable of disseminating infection twenty-four hours afterward. (3) Dysentery bacilli have been isolated from wild flies coming from places where bacillary dysentery is both endemic and epidemic. He suggests that the following points be investigated: (1) The vitality of dysentery bacilli in water, (2) the relationship of flies to bacillary dysentery, (3) the inagglutinable strains of the Flexner group, (4) the toxins of the dysentery bacilli, and (5) the preparation of a more suitable anti-serum."

Abel and Loeffler[17] report an epidemic of dysentery explosive in character, 378 cases resulting from eating an infected potato salad. The mortality was extremely low, only eight deaths resulting. Precautions were taken to prevent the further spread of the infection by (1) exclusion of further infection from the kitchen, (2) proper isolation of cases to prevent spread of infection from them, and the usual daily inspection of the kitchen personnel and food and the rigorous enforcement of personal cleanliness.

Gettings and Douglas[18] show that the biochemical reactions with 285 strains of the Flexner-Y bacilli with a small selected number of carbohydrates is a preliminary means of identification of numbers of the coliform group of bacilli, but with the closely related bacteria such as the Flexner-Y group of the dysentery bacilli it is impossible to make a classification into definite sub-groups by even an extensive use of carbohydrates. By the use of the method of the absorption of agglutinins, he found that it was possible to classify ninety-two out of ninety-five strains of the Flexner-Y group into four sub-groups. They suggest that the subgroup three may be identical with the group usually indicated as the Y group of the dysentery bacilli.

Tropical Sprue

Wood[19] shows in his article that tropical sprue undoubtedly exists in the United States, especially

19. Wood: Jour. Am. Med. Assn., 1919, lxxiii, 165. United States Naval Med. Bull., 1919, xiii, 449.

in the southern districts, and points out that there should be little difficulty in differentiating a sprue tongue from that of pellagra. He also states that the anemia of sprue resembles pernicious anemia. Livingston, in his discussion of the paper, thinks that beta-naphthol may prove to be of great therapeutic value in the treatment of the disease. Wood calls attention to the absence of skin lesions in sprue, which may well seem to distinguish it from pellagra. As regards mouth conditions, there is always a marked salivation and the tongue is of a marked carmin tint in the pellagrin. The stools of the pellagrin as usually liquid, more frequent, and occurring at any time, while those of sprue are large, frothy, and occurring more frequently in the early hours of the day.

Little advance has been made in treatment of diseases such a typhus, cholera, and plague. They all remain more or less a question mainly for the sanitarian. Friedberger[20] has, however, raised the question as to the value of cholera vaccines, and very clearly makes a comparison between inoculated and uninoculated cases in communities where cholera has been explosive in onset and has also as suddenly disappeared; often the abatement has been as rapid in unvaccinated communities as in the vaccinated. Nevertheless, the consensus of opinion seems to attach some value to cholera prophylactic vaccination.

Helminthiasis

Lucke[21] has published a very interesting statistical study of the prevalence of intestinal worms in troops. He reports 11.5 per cent infection out of 35,000 cases examined. These troops were entirely residents of southern states, yet the figures are instructive, for they give a fair average of the intestinal infections. The study is quite instructive, listing some fifteen different types of infections.

Fairley's[22] article on "Bilharziasis" is very interesting. He reports the demonstration of antibodies by the complement-fixation test and calls attention to the fact that B. mansoni were never found in the lungs and that pulmonary lesions are mainly limited to B. hematobia. Massive papillomatous formations of from 5 to 8 mm. are usually found in the bladder in B. hematobia infection.

Christopherson[23] maintains that antimony is a specific cure for bilharziasis. He bases his opinion on the results obtained during its use in the Khartorum Civil Hospital since May, 1917. He claims that it not only kills the adult bilharzia worms but later on affects the embryos in the ova in the tissues and thus prevents carriers resulting from acute infection. He again impresses the need of caution in administering the drug and suggests that less than 25 grains in all of antimony tartrate is sufficient amount to effect a cure. A marked improvement in the urine is noticeable usually after the fifth day, when only 3.5 grains have been injected. Eggs will not hatch after about 12 grains have been given. Suspected relapses are said to be due to the elimination of dead ova. The author combats vigorously the view that antimony tartrate given intravenously produces tachycardia.

There are several tropical diseases which might come under a miscellaneous heading, but most of the work done along these lines is purely experimental. However, McCarrison's[24] work on beriberi as a deficiency disease must be mentioned. The investigation is divided into three parts, (1) the effects of vitamine deficiency, (2) effect of diet too high in carbohydrates and deficient in vitamines, (3) the latter plus the influence of toxin or bacterial agencies. He concludes his article by giving eighteen general conclusions which show the thoroughness of the work and also the author's knowledge of his subject. McCarrison is quite of the opinion that diet plays a great rôle in beriberi but that in addition there are endocrine disturbances that mask the general clinical manifestations and produce variation in the types of disease. He states, for instance, that wet beriberi and dry beriberi are essentially the same, the former differing from the latter in that there exists a greater derangement of the adrenal glands. Another conclusion especially of marked interest to investigators of deficiency diseases is that infections and parasitic agencies may often be of great importance in determining the onset of symptoms.

We might continue and mention the various other interesting researches that have been carried on by numerous investigators, but since these are of interest mainly from an experimental standpoint, they will be omitted. Thus we hope that the profession can readily see that an interest in tropical medicine is of growing importance, and it is rather imperative that any member be able to meet these situations as they present themselves, despite the fact that they are infrequent.

RETARDATION FROM HOOKWORM DISEASE

Examination tests among United States soldiers by the International Health Board demonstrated that many full grown soldiers who harbored comparatively few hookworms had the mentality of persons only twelve years of age. The mentality of 10,000 white men at Camp Travis who harbored the disease was about 33 per cent below normal.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

HEADS NATIONAL ORGANIZATION FOR PUBLIC HEALTH NURSING

MISS EDNA L. FOLEY was born in Hartford, Conn. She attended the public schools there, and was graduated from Smith College in 1901. Her training in the profession of nursing was received at the Hartford Hospital Training School, her course being completed in 1904; her first professional connection was in the position of head nurse in that institution.

MISS EDNA L. FOLEY, Chicago

Her training as a nurse was particularly auspicious, as it was received under the direction of Miss Charlotte Brown, whose fine personality exerted a strong formative influence in shaping Miss Foley's career. She then became head nurse in Child's Hospital, Albany, N. Y., and for one year she served as Night Supervisor, Children's Hospital, Boston, Massachusetts.

The next succeeding year and one-half as Tuberculosis Visiting Nurse in Boston brought her into close contact with Miss Elizabeth Upjohn, the first superintendent of tuberculosis nurses in Boston. Miss Upjohn embodied the best type of socialized nursing. Her death at the untimely age of thirty-five robbed the profession of one of its best representatives. This tuberculosis service in Boston, first organized by Miss Upjohn, was really pioneer work, as Boston was the third city in the United States to put on tuberculosis nurses.

In 1909 Miss Foley came to Chicago as Superintendent of Tuberculosis Nurses, and in 1912 she became Superintendent of the Visiting Nurses' Association. In the same year she was named as the First Vice-President of the National Organization of Public Health Nursing, with Miss Lillian Wald as President. She holds others posts identifying her with important work as follows: member of Executive Committee of the National Tuberculosis Association, and member of the Board of Directors of the American Child Hygiene Association. She served on the Tuberculosis Commission to Italy of the American Red Cross in 1919, and was a member of the Illinois Commission on Health Insurance.

Miss Foley especially urges the need for every woman in the United States to take the course provided by the American Red Cross in Home Nursing, for the responsibility for the care of the sick rests first with the family, then with the physician, and then with the nurse. On the other hand, she believes that the standard of registered graduate nurses should be made more uniform and not lowered.

The work in home nursing inaugurated by the American Red Cross is especially to be emphasized. It fol- especially to be emphasized. No nursing program can be considered complete that does not strive to attain intelligent cooperation in the home care of the sick. It follows that if the family remains ignorant of or indifferent to the needs of the patient, physician and nurse are alike helpless. No group of professional workers can hope to negate unfavorable conditions except through the inculcation of a greater respect for the scientific care of the sick by means of the education of the mothers in the fundamentals of home hygiene.

THE CALL FOR PUBLIC HEALTH NURSES

THE calls for public health nurses multiply in many directions. New activities are opening and the growth of old activities is keeping pace. The figures of the growth of public health nursing are impressive. In 1901 there were only 136 public health nurses. In 1919, a census showed more than 8,000. There are somewhat more than 10,000 in service today, and of these upwards of 1,500 are working as industrial nurses—an unknown specialty fifteen years ago. It may be conservatively estimated that fully 50,000 public health nurses will be needed to meet the demands within the next ten or fifteen years.

The *Health News* of the New York State Department of Health calls the present situation an emergency, and in a recent number they state the need as follows: "The constant calls for nurses, both for public health work and for bedside nursing, indicate that the demand for nurses is far in excess of the supply. Many excellent positions are going begging throughout the country owing to inability to find competent nurses to take these places, and the opportunities open to the nurse, especially to the public health nurse, are broader than ever before. If this demand is to be met, if public health nursing is to expand and develop as it must, there is an imperative need of recruiting more young women to study for the profession, and in this most important work health officers, health and

nursing organizations, and school teachers can render a service of the highest value to the community."

In the emergency the Department announces an opportunity by bringing the knowledge of the opportunities for service to the attention of prospective students. "If the opportunities open to the nursing profession were brought to the attention of the many young women who are shortly to graduate from the schools and colleges of the state, undoubtedly much would be accomplished. Ten-minute talks before the older students will probably do much good and, whenever practicable, may be supplemented by motion pictures which may be obtained without charge from the State Department of Health.

The pictures may be shown in the leading school of the community, if fitted with projection apparatus; or it may be possible to obtain the use of some hall, church, or perhaps a motion picture theater, to which all the older school girls should be invited." The Department specially recommends the film "An Equal Chance," prepared by the National Organization of Public Health Nursing as a means of arousing interest in the opportunities in the newer phases of the profession.

IRREDUCIBLE INFANT MORTALITY

It should first be mentioned that formerly the opinion was held that deaths under one month were 75 per cent irreducible—that is, it used to be thought that these deaths could not be helped, that the causes were beyond our control. Now we know better. We do not believe a word of the irreducible theory. The death-rate under one month where the baby's father is a doctor, a merchant, or an artist is below 25 per 1,000 births; and where the baby's father is a miner, a navvy, or a scavenger, the death-rate under one month is 45 per 1,000 births.

Again, the death rate under one month in Watford, England, is 19 per thousand births, but in Workington it is 45 per thousand births. . . . Consider this: The general infant mortality rate is 100 per thousand births; but the "illegitimate" infant mortality rate is 200 per thousand births.—Helen Macmurchy, M.D.

FLORENCE NIGHTINGALE: THE PIONEER OF PUBLIC HEALTH NURSING

By MISS V. KELWAY BAMBLER, Brooklyn, N. Y.

PROBABLY to no one person does Public Health Nursing owe so much as it does to Florence Nightingale, whose centenary we celebrated on May 12, and yet to most people the story of her great work in that direction is almost unknown. It is as the heroine of the Crimea, the gentle Lady of the Lamp, that she is remembered. But that was merely a picturesque incident in her career. Her most valuable and lasting work was accomplished in the long secluded years that followed, when the public was hardly aware of her existence.

To Florence Nightingale, the first Red Cross Nurse, born one hundred years ago, attaches the distinction of lifting the nursing out of drudgery and giving it the status of a profession. (Photograph by Kadel & Herbert, New York.)

Everyone knows the story of the early part of her life. Born of well-to-do parents, brought up to a life of luxury and ease, she was never content with the quiet self-centered existence which was the lot of most of her companions. She needed always to be doing something useful, always helping someone in distress. She seemed to have been born with the instinct which in later years was to make her the "noble type of good, heroic womanhood" which she became. As a little child in the nursery, when her sister cut up her dolls, Florence patiently collected the sawdust, stuffed them, and sewed them up again. As she grew older, it was her greatest pleasure to ride around her father's estate with the Vicar as he visited his sick parishioners. She would go into the cottages, carrying comforts and medicines to the ailing, doing what she could to alleviate their sufferings. But she soon realized that there was very little she could do for them unless she could acquire at least a rudimentary knowledge of the nature of their disease, and the proper way to treat them.

And so her family was suddenly electrified by a request for permission to enter Salisbury Hospital. Such a thing was unheard of. She might just as well have asked permission to become a chimney sweep. At that time nursing, such as it was, was looked on as a most degrading profession. The hospitals were full of the worst type of women, callous, immoral, addicted to drink, unable to carry out even the simplest medical instructions. It is not surprising that her family objected. There were tears and hysterics on the part of Mrs. Nightingale, and Florence was persuaded to give up the idea.

To all appearance she abandoned the plan, but, thwarted in her purpose, she studied in secret. Pamphlets, medical works, statistics—anything she could find on the subject she devoured. When the family moved to London for the season, she would slip away to work in the slums when-

ever she could escape from the social round of her set. When the family traveled on the Continent, she would seize the opportunity to study the health conditions and the care of the sick in the great capitals. While her mother and sister were visiting picture galleries, Florence was visiting hospitals. There was hardly an institution of the kind in Europe that she did not inspect and, on one occasion, when her family were taking the waters in Germany, she slipped into a hospital managed by some Lutheran Sisters of Mercy at Kaiserswerth and worked with them for three months. To the casual observer, she was still the beautiful society girl, enjoying her pleasant life; but underneath that exterior was the real woman, relentlessly pursuing her object. For twelve long years, little by little, bit by bit, she laboriously gained her experience.

Once she was almost turned from her purpose. Love came to her. But the dull specter of the married life of the Early Victorian woman rose before her—cramped, confined, and narrow. The man appealed to her strongly, but she realized that his mental outlook lacked the breadth of her own, and that marriage with him would involve the sacrifice of all her plans. She hesitated—she wavered—and then she made her decision. She could not give up her dreams of a life-time.

Long Deferred Hope Realized

For a long time it seemed as if never would she see the realization of those dreams and she went through a period of great misery, feeling that she was of no use in the world and that her whole life was being wasted. At last, however, when she was over thirty, her parents seem to have come to the conclusion that she was too old or too strong to be thwarted any longer, and she was allowed to take up the work she had craved. She became superintendent of a hospital for retired governnesses in London. Caring for a number of tired, worn out, discontented women seemed a poor task for one of her attainments, but she threw herself into it with zest, organizing and remodeling the institution till in a few months she had improved the place almost beyond recognition.

But a greater task was awaiting her. The Crimean War had broken out and the news of the terrible condition of the military hospitals in Scutari was beginning to filter through to England. The ravages of disease were causing more deaths than the cannon of the enemy. The medical organization had broken down completely and so desperate was the situation that it became evident the war itself would be lost if immediate help were not forthcoming. Here was Miss Nightingale's opportunity. It almost seemed as if Providence itself had been guiding her toward this moment. On the one hand was the great need, on the other the woman—mature, experienced, influential, free, fully prepared for the emergeney. She promptly wrote to her friend, Sydney Herbert at the War Office, offering her services. Sydney Herbert, from an intimate personal acquaintance, knew of her experience and was convinced of her capability, and it so happened that his letter asking for her assistance crossed hers in the post.

She wasted no time. Within a week she had collected a band of thirty-eight nurses and was starting for Constantinople. Before she left, she had made inquiries at the War Office as to stores and supplies and had been assured that nothing was needed. But she preferred to trust her own judgment. With the almost uncanny foresight which distinguished her throughout her life she provided large quantities of clothing, medical necessities, comforts for the sick, and even laundry equipment.

Her caution was fully justified. When she arrived at Scutari, she found a condition of filth, misery, and want beyond deseription. The Crimean officials, bound up as they were with military red tape and the still stronger bonds of a conservative conventionality, were not prepared to be helpful. She disregarded them. Quiet and unassuming, she started on her inspection. The story of what she found is almost too well known to bear repetition. A great, insanitary, ill-ventilated barrack had been

From this home Florence Nightingale went forth on her mission of "sweetness and light," visualizing a conception of nursing which has obtained until the present day and organizing what still must he considered perhaps the best possihle human service. (Photograph by Kadel & Herbert, New York.)

set aside for the wounded. It was entirely inadequate. There were no cots, no linen, no furniture, and not even the simplest medical necessities. The doctors were for the most part elderly and incompetent, and the younger men too few in number to cope with the avalanche of disease and distress which was pouring in. For four miles Miss Nightingale walked through the wards, where the men lay row after row, packed close together in a condition of indescribable filth and neglect. Think of it! Four miles of human suffering and misery. It was enough to make the stoutest heart quail at the immensity of the task, and all the while more and still more wounded were pouring in.

Relief Work Immediately Begun

Next day the work of reorganization was started. Carpenters and plumbers were brought in and while they opened out windows and repaired drains Miss Nightingale turned her attention to the kitchen and laundry. No clean linen was available for sick and the only food provided for her patients was the ill cooked and often nauseating army ration. From the stores which she had brought with her, in spite of the assurance that nothing was needed, she produced her laundry equipment, her jellies and comforts, and her clothing, and in a short time the men were receiving clean linen and well cooked food. There was still a great field to be covered, and she was terribly hampered by the slowness of the military mechanism. On one occasion, hundreds of wounded lay shivering for want of clothing, while thousands of shirts were kept locked up in the warehouse, waiting for a Board to give permission for them to be unpacked. It was not long before Miss Nightingale took things into her own hands, and the next time this happened she had the warehouse forcibly opened. The authorities raged, but she had Sydney Herbert and the Government behind her.

All day she worked indefatigably, administering and organizing her hospital. Most of the night she sat up, composing voluminous official reports, keeping statistics, writing letters to the relatives of the sick, and sending long and detailed accounts of her work to Sydney Herbert. Bitter and sarcastic accounts they were, picking out unerringly the faults and failings of those around her, the futility of the military organization, and the incompetence of its officials. When Dr. Hall, the chief medical authority, was given the K.C.B. she remarked caustically that she presumed that the letters stood for Knight of the Crimean Burial Grounds. With Dr. Hall, incompetent and obstructive, she had several encounters; but her natural shrewdness and the knowledge that behind her was the approval of the whole British public enabled her almost invariably to come off victor. The gentle, unassuming woman, the romantic "Lady of the Lamp," made a great appeal to the imagination. The quiet, capable woman, with the thin, curved nose and the small, determined mouth, knew her power and made use of it to the full to achieve her ends.

Her Influence in High Places

When her task in the Crimea was at last accomplished, and the time came for her to return to England, she received a most enthusiastic letter from the Queen, with an invitation to visit Balmoral. She went, and took the opportunity to lay before the Queen and the Prince Consort a detailed account of the defects she had found in the hospital system, and the reforms she considered necessary. As the woman who to all intents and purposes saved the war, who in a few short months had reduced the mortality from 420 per thousand to 22 per thousand, 42 per cent, she could speak with authority. "What a head," remarked the Queen. "I wish we had her at the War Office."

But if Miss Nightingale herself could not be at the War Office, she had an intimate friend there through whom she could work. Sydney Herbert was her devoted admirer, their mutual bond a great devotion to the public cause. Precluded by her sex, and by broken health, from taking any active part in public life, she determined to make the successful politician her mouthpiece. Her work in the Crimea she looked upon as a mere episode. Her great task still lay before her.

Worn out by the incessant strain of the last two years, she had returned to England almost at death's door. Rest was pronounced to be the only cure. But rest she would not. How could she, when there was so much to be done? And so, in hourly expectation of death, she worked on. Confined to her bed, almost in a state of collapse, she set out to reform the sanitation and hospital system of the army, and to organize a scheme of skilled nursing for the sick poor of the country. In the face of considerable opposition from the War Office, a wonderful improvement was made in the health conditions of the soldiers and gradually she was able to turn her attention more and more to the problem nearest her heart. As a young girl, she had seen in the London slums and on her father's estate in the country the sad plight of the sick poor, and the determination to better their condition had been before her from the beginning of her career.

The outlook was not encouraging and many people believed that it was a waste of time and energy to attempt any healing work in the dirty and insanitary homes of the great cities. Miss Nightingale thought otherwise, and presently there came an opportunity to make her first experiment in this direction. At this time the only nursing available for the sick poor was in the workhouses, where the attendants were paupers themselves, dirty, callous, and untrained, and where the general misery and neglect were beyond description. Mr. William Rathbone, a Quaker of Liverpool, wished to devise some scheme for the improvement of this state of things, and wrote to Miss Nightingale for her advice. At her suggestion he built a Training School for Nurses who should replace the old Infirmary attendants and eventually extend their care into the homes of the sick. From the Nightingale School for Nurses which she had founded at St. Thomas' Hospital, she provided a superintendent for the Infirmary and twelve nurses. Against a mountain of disease and disorder these pioneers worked patiently and courageously and, so great was the success of this first experiment in public health work, that Miss Nightingale was encouraged to work for the same reform in London. It needed hours of planning and organizing from her sick room, and it was not till 1867 that she was able to get a better system introduced into the London workhouses.

District nursing prospered beyond the most sanguine expectations and a great impetus was given to it in 1887, when Queen Victoria presented £70,000 of the Women's Jubilee Offering to the Association. But to the end of her life Miss Nightingale was working for the perfecting of this long planned scheme, reorganizing the methods of work, drawing up requirements of training, and urging the necessity of keeping statistical records. In fact, not a single detail did she overlook. Before her death in February, 1910, public health nursing was firmly established. It remains for us to see that the Lamp she lighted burns ever more brightly, till there is not a corner in the darkest home in the country into which its rays do not penetrate with their healing influence.

HELIOTHERAPY, open air schools for the pre-tuberculous, and manual training for the feeble-minded are here shown as typical parts of child welfare work in old Italy. Stazione Elisterapica, Genoa, located on the beach, is sheltered from the north winds and has an exposure which gives it a temperature from two to four degrees above that on the street which is on a level with the roof of the house. The children are shown at lunch, and on the terrace undergoing the sun-cure.

The Open Air School on the strand holds its winter sessions in this public seabath hous. The Asilo, or Open Air School at Genoa, is a home provided for the well children of tuberculous parents by the Genoese Anti-Tuberculous Association. Similar homes are maintained for children who have been infected.

The manual training class is from the "Senola Antonoma" for deficient and backward children, Genoa. *(Pictures supplied by Miss Edna L. Foley, Chicago, during her service in Italy on the Tuberculosis Commission of the American Red Cross.*

WISCONSIN WELFARE WORKERS ASSOCIATION *

By MISS MARY LA RUE, Chairman, Committee on Home Visiting, Milwaukee, Wis.

IN the estimation of your Committee, nothing seems more fundamental for the happiness and well being of the industrial workers than a feeling of contentment and happiness which finds its origin in a friendly exchange of ideas between employer and employee. In this connection the home visitor has become an important factor in modern industry. It has been demonstrated that activities along lines of health and comfort, when properly directed, not only reduce accidents and illness and raise the standard of living, but also give direct results in increased efficiency and production of work in the factory.

Service Not a Charity

Home visiting of a patronizing nature never yields satisfactory results. It must be whole hearted and, above all, it must encourage the independence of the employee. Any feeling that the people visited are receiving charity naturally would be resented. Corporations should realize this work is merely additional factory output and that the money expended is a profitable investment.

The obligation of industry is not covered by the mere payment of wages and direction of works. It uses up human life and it is therefore under moral obligation to protect what it cannot use in the individual worker's life after extracting the serviceable and leaving only waste. Home visiting can be made a recognition of this fact and is an endeavor to remedy this defect of modern industrial life. Many industries have done much; much more remains to be done. The majority of the great industries are studying and experimenting with possibilities to ascertain and follow the best methods of bettering the conditions of their employees.

The scope of work in the home is almost unlimited, being determined by the desires of the firm and the kind of a home visitor employed. To a large extent the firm decides what line of work will be done, but, without creating opposition, a tactful and earnest worker can enlarge on work laid out, and many times can make his or her work invaluable in this way both to employee and employer.

Entrance into the home is gained through illness or accident, because of domestic or financial trouble, or through the absence of employee without notice. Requests for these calls are received direct from the employee himself, from his foreman, or some fellow worker to whom he has confided his troubles and who wishes to help him out.

A Get Together Policy

The aim should be to see that the employee gets a square deal and to assist him and his family during times of misfortune or illness. A tactful visitor having common sense and the ability to get in touch with people, becomes a connecting link between the man's work and his home, is able to make him feel that his employer is really interested in his welfare, and at all times has her finger on the pulse of situations in factory. Shop affairs are discussed in almost every working man's home, and getting their views gives a good insight into attitude of workers.

By discussing with the foreman unsatisfactory factory conditions complained of, such conditions can very often be remedied and a source of discontent removed. By gaining confidence, the home visitor usually has very little trouble in overcoming opposition to proper medical attention, needed operations and improvement in housing conditions when necessary. As far as possible, the visitor should endeavor to teach the family to help itself, which in many cases can be accomplished by the extension of a small loan without interest. In periods of distress, when the head of the family is out of work because of accident or illness and the funds have become exhausted, it sometimes becomes necessary to extend financial assistance not in the form of a loan. In such cases the home visitor should have the authority to promise definite financial assistance within certain limits. To be effective, such aid should be prompt, and by her ability to announce a definite cash contribution a great deal of the worry of the family would be promptly removed. Such acts of mercy will do more toward achieving an adjustment of a crisis in labor relations than the application of any scientific method.

A home visitor's knowledge of existing agencies, free dispensaries, hospitals, convalescent homes, and relief societies, and her ability to secure more considerate rates for dental work or much needed medical or surgical treatment, are of immense value in her work.

It often becomes necessary for a visitor to make suggestions on topics of public health, to offer possible solutions for domestic troubles, as well as to be able to discuss various topics which might enter into the home life, which prove to be invaluable in assisting the family. A knowledge of housing conditions is very important in order to be able to advise the family in regard to such possible insanitary conditions as damp basements, lack of sufficient light, or the inability to obtain sufficient ventilation, particularly in the bed rooms. By getting a family out of an insanitary home and into more hygienic quarters an improvement in the health of the family usually becomes immediately noticeable. The home visitor should be able to impress on the mother of the family, for instance, that ventilation and cleanliness cost little or nothing, that flies in the summer are unnecessary, and huddling together at night of large numbers of people, especially children, is hurtful.

Achieve Better Relations

Working with foremen and others in authority instead of antagonizing them, using influence rather than authority in gaining a point, will help to create a better feeling and remove much of the opposition to social work. In this way it is easy to secure suitable employment for a man returning to work after a serious operation or illness or, in cases where necessary, an entire change of employment.

While records of family conditions and visits are a necessity, it is not at all desirable to try to get complete information during the first visits; in fact it is preferable to get the information without the family realizing that any record is being made of the data secured. In order not to offend them no notes should be taken during the visits, but the home visitor should practise remembering the data secured, setting them down after leaving the house or on reaching the office.

Likewise, no attempt should be made to teach the family at the first visit all the points which the home condition

*Report to the Wisconsin Welfare Association by the Committee on Home Nursing, made under date of March 1, 1920.

might suggest; but, rather, attention should be centered on one or two of the most important points and the rest be left for subsequent calls.

The success of the work of the home visitor will largely depend on the manner in which she makes her first entrance into a home. No definite rules can be laid down. Circumstances and conditions must dictate to the tactful worker the proper approach to make. Intimate knowledge of home conditions often brings the visitor in touch with situations which would not for many months be recognized as abnormal by others.

The power to sow the seeds of discontent and unrest is just as potent as is the power to distribute a spirit of loyalty and appreciation and greatly strengthen the bond between employer and employee. The visiting welfare worker is in position to explain and obliterate misunderstandings and ill feeling arising between foremen and workers, and through courteous tactfulness remove the personal animosity and jealousy which all too often prove a cause for an increasing turnover and absence from work. She will proceed slowly at first and in visiting families must not allow zeal to carry her along too fast, but must try to add to her social attitude of mind an outlook on the business aspect of the various situations. There should be no sentimentality or one-sided point of view about work. Nothing is more important than the value placed upon her work by the employees themselves.

In plants where a messenger is not employed, the visitor often receives a daily list of absentees on whom a routine call of inquiry is made to find out the cause of absence. It rests with her to make these visits agreeable and to avoid all appearance of having been sent to spy on the employee, not a difficult matter unless she is signally lacking in tact.

The Agent of Service

Home visiting is usually carried out by one of the following: visiting nurse, service worker—man or woman,—or a visiting housekeeper, supplemented by messenger service. In some plants several of these different types of workers are employed, the combination of visiting nurse and messenger service being the most frequent. In some of the smaller shops it is not unusual for the visiting nurse to spend several hours in the morning supervising the first aid room, and the rest of the day in making calls. In larger plants she is relieved entirely of any connection with the shop hospital or the first aid room. Where a number of smaller plants are located in close proximity to one another, one visiting nurse can easily manage to supervise the first aid work and do the visiting work of the plants as well.

A great deal of comfort and happiness is created by the visitor on calling on the sick people, either in the hospital or in the home. The distribution of carefully selected plants, flowers, or magazines is a wonderful means of shortening the otherwise tedious hours for a patient recovering from serious illness. A few thoughtful acts along this line on the part of the visiting nurse will always be gratefully remembered.

In some plants a visiting housekeeper has been employed to supplement the work of the visiting nurse. It is her duty in cases of serious illness, particularly in the case of the mother of a family, to spend part or all of the day in doing the work which the mother is unable to do because of her illness. In other words, she takes complete charge of the housework, thereby enabling the employee to return to his work, his mind at ease, knowing that the family is well taken care of and that he is earning his usual wage. This effects a decided gain for the employer on account of averting the necessity of securing another man for the position, or having a machine idle. Such a housekeeper, properly trained, has abundant opportunity to teach the family the best methods of preparing wholesome dishes for the children and proper methods of hygiene and sanitation. Much more can be accomplished along these lines than by an occasional visit.

Qualifications of a Home Visitor

Regarding the qualifications of the visiting welfare worker, your Committee believes that only those should serve in such a capacity who have a thorough educational preparation; who have an intelligent understanding of social customs and conditions among the working class; if possible, those who can master one or more languages spoken by foreigners; and who not only are thoroughly familiar with American ideals, but also know how to preach and apply them.

Pleasing personality, good health, and endurance are essential, as are sound judgment and tact, and ability to use discretion on all occasions. She should be full of human sympathy, be able to see the humorous side of life and to view situations from an unbiased standpoint. She should have a thorough knowledge of the policy of the company and ability to convince the employee of its fairness, and that he has a really good place to work. She must be able to convince them that she is their friend and that they can tell her in confidence whatever troubles they may have on their minds. Because of the importance of properly impressing a family, a visiting nurse should always be a graduate nurse. The home visitor may be a practical nurse, although not necessarily so. The visiting housekeeper preferably should be a practical nurse as well as a good housekeeper.

Before working alone as industrial visiting nurse or as a service worker, such a person should receive definite training in industrial service with a worker who has a thorough understanding of plant conditions, thus avoiding possible damage because of lack of proper knowledge of the fundamentals which she has to deal with in visiting the homes.

To Whom Responsible

In order that the work may be of real value, it is exceedingly important to decide the question as to whom the home visitor should be responsible. Responsibility of reporting should not be to a foreman or superintendent, but to some higher official of the company, unless the plant has a well organized welfare department with a manager in charge. In the work of the visiting nurse or home visitor so many questions come up that have to be settled and settled quickly, questions that frequently involve financial outlay either in direct allowances or in the form of a loan, questions of assuming medical or hospital bills, that a quick decision is necessary in order that the work of the home visitor may be most effective.

A definite and rather fixed policy should be adopted for her guidance, in order that she may know just how far she may go in making a definite promise or, at least, in suggesting what she is willing to call to the attention of the firm for their action and attention. Any promise made on her part and not backed up by the corporation will have a decidedly detrimental effect. The home visitor is frequently asked for advice and suggestions in regard to family and legal matters and she should have someone whom she may call on for legal information in order to inform the family what their rights are and what is the best course to pursue.

While there are such agencies as the Legal Aid Asso-

ciation and similar bodies which aim to deal with the unfortunate in distress, any employee of an industrial plant should never be forced to call on agencies whose work might readily be considered as charity. Any work of this nature ought by all means to be rendered by the employer, thereby helping to maintain the employee's self-respect, because the employee considers that whatever is done along lines of this nature by the employer is due to his interest in him and something to which he may justly have a right to expect attention.

In summing up, no visiting nurse or home visitor should be engaged and started out until the person to whom directly responsible has been settled, in order that there may be no shifting of authority, which is bound to have a bad effect on her.

Records are Important

The importance of records must not be overlooked, but, on the other hand, they must not be over-emphasized. While it is important to have complete record, it is just as important to realize what is essential and what is not, thereby avoiding confusing the records with information that can have no possible future value. Records of family conditions must be considered absolutely confidential and only available for those persons who have a right to the information. While the record cards should provide spaces for complete information, not alone in regard to housing and living conditions and conditions of the home, but also about the members of the family and their condition from a health standpoint, such stress must not be laid on the records and the collecting of facts that the real work of the visitor is neglected in order to fill up the card with information. In entering visits on the cards, facts and not emotions should be the guide.

In closing, will quote from Miss Edna L. Foley's admirable article in *The Modern Hospital*, August, 1916, on "The Visiting Nurse in Industry":

Too often an industrial visiting nurse is but a well trained, well intentioned woman with no special preparation for an important piece of sociological endeavor. Such a nurse can do good work, but she can rarely do the big constructive piece of honest welfare work desired by most employers. The position of visiting nurse for any firm should be one of dignity as well as of responsibility. No nurse should be engaged because her knowledge of illness and minor accidents may enable the firm to dispense with the services of a paid physician, for a nurse is not trained or licensed to practise medicine, neither should she be engaged to follow up absent employees who are suspected of malingering. Nor can she do the best work for employees if she spends the better part of her working day in a little dispensary waiting for accident cases. A comprehensive plan of good industrial visiting nursing includes a staff of nurses large enough to enable the firm to have a nurse on hand for emergencies, and other nurses for home calls.'

For further information along this line we would recommend the following magazines and books:

Magazines.—The American Public Health Journal, The Modern Hospital, Modern Industry, MODERN MEDICINE and the various nursing journals.

Books.—Personnel and Medical Audit, by F. E. Weekly; Relations of Home Conditions to Industrial Efficiency, by M. B. Gilson; Welfare of Factory Workers, by A. Shadwell; Welfare Work, by L. Amy; and Work and Service of the Factory Nurse in Manufacturing Plants, by N. C. Rudd.

RESTRICTIONS ON NARCOTICS

Osteopaths in Minnesota may no longer issue prescriptions for narcotic drugs in that state, this being in accordance with a recent ruling by the attorney general.

PROBLEMS OF NURSING EDUCATION

The American Conference on Hospital Service, which met in Chicago on March 3, appointed a Committee on Nursing. The members of this Committee made a resolution to study the nursing problem as it exists today, both in the United States and Canada.

If you are interested in nursing problems, will you answer the following questions and mail your reply to Miss Elnora Thomson, School of Civics and Philanthropy, 2559 South Michigan Avenue, Chicago, Ill.? Miss Thomson is a member of the Committee, and is desirous of securing data from various sources on which to base a study of the problems before the next meeting of the Conference, which is to be held in Montreal, on October 4, 1920.

(1) What is your opinion of the three-year course for nurses connected with hospitals? The two-year course? The high school pre-nursing courses? The Red Cross extension courses? Short courses and correspondence courses?

(2) Are the principles laid down in the nursing education in these courses right or wrong? If right, how can it be improved so as to adequately meet the nursing need? If wrong, how should the training of the nurses be made right?

(3) What use are the graduates of these various schools making of this training?

(4) What misuse are the graduates of these schools making of their training?

(5) What, if any, is the nurse wastage during training?

(6) What, if any, is the nurse wastage after finishing their course?

(7) What are some of the reasons for the shortage of nurses today?

(8) What suggestions can be made as to changes in the training to make it efficient and not lower the nursing standards?

HEALTH LECTURES FOR TRAINING SCHOOLS

The Joint National Committee of the American Nurses Association, National League of Nursing Education, National Organization for Public Health Nursing, and the American Red Cross has prepared and is offering a series of lectures on public health nursing to be read to student nurses by an authorized public health nurse reader, who can answer questions on the subject. The series covers the following subjects: (1) Achievements and opportunities in the field of public health nursing. (2) Visiting bedside nursing: industrial nursing. (3) Prenatal, maternity, infant and child welfare nursing: conferences. (4) Tuberculosis nursing and the nurse in the venereal clinic. (5) Medical social service and medical hygiene. (6) The public health nurse in relation to community development.

These lectures can be secured by application to the National Headquarters at 156 Fifth Avenue, New York City, or the Central Branch Office, Room 904, 116 South Michigan Avenue, Chicago, of the National Organization for Public Health Nursing. The lectures have been prepared by experts in the various public health nursing branches in response to a demand for such material from the superintendents of training schools. It is the desire of the Joint Committee to keep the lecture material absolutely up to date. They, therefore, have numbered each of the offices after they have been read to these special groups of students.

The interest in public health nursing should result in more women entering the special courses which have been organized for the training of public health nurses.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

BOGUS PROPAGANDA

THE New York State League of Women Voters has signalized its entrance into the field of public action by a notable report and protest made to the governor, the legislature, and the people of the state of New York. The League has been for some time backing certain welfare legislation, including the minimum wage for women, the eight-hour day for women, and workmen's health insurance. These projects had been blocked in the legislature and they instituted a careful investigation to find out the reasons.

"We have found," they said, "that there exists in New York state a dangerous subversion not only of legislative opinion, but of public opinion as well. We have found a condition by virtue of which it is evident that it has been made exceedingly difficult for any constructive social or industrial measure to get adequate and unbiased consideration before either the public or the legislative opinion of the state, and we have found that the influences at work, so far from being invisible, are flagrantly and cynically open and are rapidly becoming notorious."

The direct attack of the League was made upon the Associated Manufacturers and Merchants Organization and their subsidiary organization, the so-called New York League for Americanism. The pamphlet which has been issued by the League is well worth study and consideration by every person interested in the honest workings of democracy. It shows the power of propaganda in the hands of special interests backed by ample finance. It shows the relationship between certain commercial insurance interests and the opposition to welfare legislation.

As illustrative of the methods pursued, the report goes on to state regarding the propaganda of the so-called League for Americanism: "It has misstated the effect and methods of operation of proposed industrial legislation. It has grossly exaggerated the cost. It has sought to lead industrial workers into believing that such measures would deprive them of their individual rights.

"It has misled physicians and prevailed upon them to organize under the auspices of the 'League' into so-called 'Professional Guilds' by creating the impression that professional fees under the proposed workmen's cooperative illness insurance measure would be reduced as low as fifty, twenty-five, and even six cents; whereas it should be well known that the bill provides that professional fees shall be on a basis initiated by the various county medical societies.

"The 'League' has associated itself with and brought into the scheme of operation individuals who have been given to the most inflammatory and unfounded statements and innuendos. In the form of so-called 'boiler plate' it has repeatedly sent to the numerous daily and weekly up-state newspapers propagandist material as false and misleading as any that could be devised.

"The 'League' has gained circulation for such statements not only through the press but through paid orators, and has shown singular energy in hiring speakers to attack proposed industrial legislation on the basis of the League's own tricky assertions. It has particularly sought to create the impression that such legislation is of pro-German and Bolshevik origin."

The medical profession and public spirited citizens generally throughout the country will read this report with keen interest. There is not lacking evidence that the same propaganda is nation-wide. Beginnings have been made in a number of states where welfare legislation has been advanced to organize the same type of propaganda under more or less thinly veiled disguises. With paid workers and ingenious publicity bureaus, this propaganda approaches a national menace.

TRENDS IN THE DEVELOPMENT OF SCIENTIFIC MEDICINE*

By FRANCIS MARION POTTENGER, A.M., M.D., LL.D., Monrovia, Cal.

The ultra-refinement of laboratory method has led to illogical specialization which has caused an unfortunate abstraction on the part of the physician and a defection on the part of the patient to various cults which place the greater emphasis on the personal equation.

In the final reorganization of medicine socialization with its tendency to disorganization, and group medicine with its effort to overcome the weakness of specialism, will be looked upon as steps in the development of a modern clinical medicine in which the whole will assume its proper relationship with its parts, will assure more efficient service.

THE office of president is the highest honor that any organization has to confer upon its members. The presidency of the Mississippi Valley Medical Association, however, is a special honor, because of the fact that it is one of the largest and best general medical societies in the United States, and because of the character and achievements of its members. To say that I thank you for conferring this honor upon me, but feebly expresses the gratitude which fills my heart. It is an honor to be associated with the people of this great Mississippi Valley because they partake in thought and ideals of its own bigness and vastness. This liberal spirit you have shown in going to the far West to confer the presidency upon me. I have always endeavored to give this society my best effort; and now as I become one of your ex-presidents I hope I may continue to be a faithful worker for the good of the organization.

The Altruism of the Profession

The two years which it has been my privilege to serve as president have been years of unusual sacrifice on the part of the members of our profession. Never has greater unselfishness been shown by any group of men. Many of our own members, along with physicians from all sections of our country, left their homes, and practices which they had acquired after years of work and struggle, and gave their time and knowledge to the cause of their country without regard to personal consequences. Never could a man say with greater truth that he is proud to be a physician than now after seeing the worthy sacrifice made and efficient service rendered by the members of our profession during the world war.

Medical science put the most efficient armies into the field that were ever massed for combat. While the scientific agencies of destruction were all concentrated for killing men, the scientific agencies for preservation and reconstruction were also thoroughly organized for saving life. While more men were killed in combat than in previous wars, fewer died of disease and of wounds. The medical profession emerges from this war with the honor of having been able to amass millions of men together under most unfavorable conditions and still keep the rate of illness among them below what it was for the same group of men in civil life. And now that the war is over our profession is still putting forth its best efforts for the reconstruction of those who were disabled.

Our profession which acquitted itself so nobly during the months of training and combat is now again adjusting itself to civil life and applying itself to the solution of the new questions which result from the overturning of the old order. It has been eminently successful in maintaining the efficiency of the uninjured soldier and in reconstructing those who were injured. May it be equally successful in increasing its own efficiency and in reconstructing itself to meet the demands which are to be made upon it by the new regime which is being established.

A Fourfold Service

Medicine is able to perform four great services for mankind; services which largely influence the lives and determine the happiness of the people: (1) the prevention of disease; (2) the cure of disease; (3) the relief of symptoms and suffering; and (4) the increasing of the efficiency of those who are subnormal. The prevention of disease is desirable for everybody; consequently there are one hundred million people in the United States whom this interests. It is estimated that the total acute illness of the United States alone is equivalent to ten days illness per person annually. A great deal of this as well as much of the chronic illness is accompanied by troublesome

*President's Address; read before the Forty-fourth Annual Meeting of the Mississippi Valley Medical Association, at Louisville, Ky., October 21, 22, and 23, 1919.

symptoms and suffering. Therefore a large percentage of the population is interested in the cure of disease and the relief of symptoms. The selective draft as well as inspection of school children and factory and shop employees has revealed a tremendous amount of unfitness among children and the young adult population. Many of these conditions may be remedied wholly, others in part; so there is an enormous demand made upon the profession to increase the efficiency of the unfit.

It would seem, then, that the opportunities for rendering service, and the demands made upon the medical profession are almost limitless. A profession which shows itself capable of rendering such service to the human race should hold not only an important but an intimate and confidential place in the hearts and estimation of the people. But let us inquire, does it hold the position of power and honor that is warranted by the service which it is able to render?

The Family Physician Passing

If we critically analyze the situation, we find that the medical profession has temporarily lost some of its former prestige. We further find that it began to lose prestige coincident with the great discoveries which increased its efficiency and made it capable of rendering better service. This was the era which marked the passing of the old family physician. It was the time when mysticism gave way to scientific fact; when the interest in the patient who had the disease was transferred to the disease which had the patient. The family physician, the counselor and friend in time of sickness and trouble, the advisor when new enterprises were contemplated, gave way to a new order in which the doctor became a student of scientific medicine, a student of tissues, germs, secretions, and excretions rather than a student of human beings and human nature. The practice of medicine became more scientific, but less personal.

The public noticed with regret that the interested counselor and family friend was passing, and the new medicine failed to convince the people that the new practice based on greater knowledge is better than the old. So medicine relinquished that intimate hold on the people, which it had always possessed, and the people began searching for something to take its place.

During this period of transition, many cults and isms sprang up, each attempting to supply that which the medical profession had abandoned. New Thought, Christian Science, Osteopathy, and Naturopathy are a few cults that might be mentioned.

Each one of these cults has something that the people want; otherwise it would not exist. Some have very little and they soon pass away. Not one of them possesses anything that medicine does not have; in fact, they are all limited in the service that they can render; yet, in spite of this limitation, they have gained a certain recognition and in some quarters a large following, largely because of a failure on the part of the public to appreciate the value of scientific medicine. An analysis of one and all of these pathies shows one common characteristic which makes for their success—they all emphasize a personal rather than a scientific interest, an attempt to help the patient rather than to attack the disease. The personal attention, the patient likes. Not appreciating the modern scientific facts regarding disease, it is but natural that these cults should underrate its importance. Their attitude is much the same as that of the old physicians in prescientific days. The mental healer and the Christian scientist see only the mental side of the patient and treat him as an individual with disturbed lines of thought. If they are able to secure his confidence they help him to just the extent that he can be helped by relieving a bad mental attitude. In some instances this is much; in others little. The osteopath massages and makes some patients feel better. The naturopath prescribes simple measures and regulates the patient's life, and thus helps a certain number. The success of these narrow cults should show scientific medicine wherein it is lacking; for their success depends, one and all, upon their interest in the patient. Medicine should again become more personal. This it can do without becoming less scientific, and to the advantage of the patient as well as the profession.

There is no use in our denying that each cult is capable of doing some good in its narrow way. But why should any cult so narrow in conception as to ignore the vast fund of accumulated scientific knowledge, exist and receive recognition? There is but one answer. It satisfies a demand. Medicine can fulfill all the requirements that are met by Christian scientist, mental healer, osteopath, or what not, and do it in a scientific way. It has the knowledge of the disease and the knowledge of the patient, and it should combine them in such a spirit of broad-mindedness as to meet the requirements of the people. Will this be done?

The Prevention of Disease

Of the four great services that the medical profession is able to render to the public, the prevention of disease is the greatest. This stands out as

the highest ideal to be attained by medicine. While it means the most for the human race, the race as a whole manifests little interest in this phase of the subject, and we have the double paradox of the medical profession finding its greatest interest in the one service which it is capable of rendering which will eventually curtail its earning power; and of the public finding the least interest in the one service which concerns it most and which offers it the greatest aid and security.

How can the medical profession secure the interest and cooperation of the public in the prevention of disease? This is one of the most difficult problems before it. Now that it has acquired by years of patient research the knowledge which, if applied, will materially lessen disease the profession is greatly hampered in its application by a public, apathetic, and apparently unwilling to receive such benefits. Why this attitude and how can it be overcome? It is largely due to a failure on the part of the public to grasp what preventive medicine means, and a suspicion on its part of the disinterestedness of the profession in advocating it. It can be overcome only by securing the confidence of the people and making them appreciate that preventive medicine is for them, and not for the profession. The profession of medicine has become too much medical. It has held itself aloof from things social, industrial, and political with the result that it is not able to make the power of modern medicine stand for what it is worth.

Unless medicine is able to impress its worth upon each generation through which it passes it is falling short of its duty. If the public only understood the success that would attend applying scientific measures to the prevention of disease it would compel the government to institute the necessary machinery without delay. There would be a Department of Health in the President's Cabinet, whose function it would be to guard the health of human beings and see that all known preventive measures were put into practical application; and it would not be established at the suggestion of the medical profession against the will of an opposing public. It would be established by a demanding public, and its efficiency would be guaranteed by the fact that it would have the support of those who benefit by it.

There is a suspicion on the part of the public that anything that the medical profession advocates must have self interest as its basis. This suspicion is but natural in this materialistic age, in which the wits of one group enables it to live off of another group; and, in the final analysis, this suspicion of self interest is based on fact; but it is self-interest in an unselfish ideal. The interest of the medical profession in preventive medicine is, aside from the desire to prevent suffering and death, the interest of a parent in its own child; for preventive medicine is the logical offspring of years and years of scientific labor.

Too much energy has been expended in talking to doctors about the benefits derived from the prevention of disease. They are already convinced. It is the lay audience that needs to understand and which should be reached. This will never be attained through addresses before medical societies or through scientific articles in professional journals, but only by methods which will reach the people and acquaint them with the facts of preventive medicine and arouse within them the desire to attain its benefits.

Increasing Human Efficiency

Along with the prevention of disease we must consider another great altruistic service which medicine is capable of rendering to the public. I refer to the increasing of human efficiency by improving the working power of the human machine.

The importance of this phase of medicine has been partly appreciated for years. It has been carried out, though imperfectly, and often half-heartedly, through examination of school children and factory employees. It has shown a high percentage of subnormal children and workers; but no one was ready to believe the extent to which inefficiency exists as revealed by our recent draft examinations. While statistics of school inspection show that from 50 to 75 per cent of school children suffer from some remediable defect, often only trivial in nature, the draft examination showed that 50 per cent of the young men in America who were within the draft age were unable to stand military service. While a large proportion of this 50 per cent may be perfectly able to fill positions in civil life, yet it should cause us to make a careful survey and see if the efficiency of these young men can not be increased. The one important fact with reference to the young men of draft age, as well as those who show defects while of school age, is that many of the defects are remediable. Some can be wholly relieved; others can be partially relieved; but there is no doubt that, if a concerted effort were put forth, the inefficiency found among the people could be greatly decreased.

Physical defects lead to wrong habits of living; and are often, in fact we might say usually, accompanied by faulty education. So the subnormal individual becomes a subnormal, physically, nervously, and psychically. The course often runs

the other way, too. Bad habits of living lead to physical defects, and nervous and psychical unbalance. In attacking this problem, medicine shows itself in its broadest aspect and applies its scientific knowledge to social and economic requirements. It is not only physical defects that are to be remedied, but nervous and psychical as well. Medicine alone can furnish the basis for understanding the whole question of man's adjustment to man and society as a whole.

There are in the United States about twenty million children in the public and private schools. Think what it would mean for the future efficiency of the race if the remediable physical defects alone of these children were corrected. It is little short of criminal to allow these children to go on without proper care. If it were due to active opposition such as that offered by those who do not recognize defects and disease, it would be; but since the fact that they are not cared for is rather due to a lack of knowledge on the part of the public, it must be excused until the necessity is appreciated. The seriousness of the offense against the growing youth, however, must be impressed upon the public in such a way that it will see, and understand, and demand that these defects be relieved.

A Test for the Socially Minded

There seems to be a gradual awakening in interest in those phases of medicine which are of a social and industrial nature; and it is probable that this interest will receive fresh impetus after our recent war experiences. Industrial and state medicine are likely to be questions of absorbing interest to our profession in the immediate future. Such movements will necessitate some change in our ideas as a profession, and may test our willingness to subordinate what seems to be the best interest of the profession to what seems to be the best interest of the state. Such movements are steps in progress and must be considered from a broad-minded, humanitarian standpoint. The profession owes it to itself as well as to the public to face such questions fairly and squarely, not in the way of self-interest, but from the standpoint of progress and the common good. Progress is made by encroaching on supposedly established rights and, while each encroachment may be temporarily set aside, yet if it is necessary to progress it will finally be established. These questions can not be settled except by taking into consideration the broadest relationships of medicine to the state.

Prior to the development of modern medicine, the relief of suffering and the cure of the patient were the chief concerns of medicine. The physician was consulted to relieve some distressing symptom or because of the faith in his power to cure a disease process. While the prevention of disease and the relief of inefficiency will demand more and more of the profession's attention in the future, as long as disease exists and as long as human beings suffer, the profession will be called upon to aid in the cure of curable ills, and to relieve pain and other distressing symptoms. Therefore, while this part of our work may not be as idealistic as the other, it is no less important. It, too, is humanitarian and thoroughly practical, and demands the best efforts of our profession.

In order to render our best service to the public we should acquaint ourselves with both the disease and the patient.

It is within the life and memory of the members of this Association that modern medicine has developed, yes, more than that—many of our members have had an active and important part in its development. The cheerful presence and the mystifying look of wisdom which characterized the old practitioner has given way to an ever present consciousness of one's lack of knowledge, which has unavoidably resulted from the rapid growth and development of modern medicine. The kaleidoscopic changes made necessary by the rapid discovery of new facts have surrounded modern medicine with an air of inexactness and imbued the profession with a lack of faith in itself. Each year has seen so many idols shattered, so many principles on which former medicine was based proved false, so many facts revealed, and evidence of so many more which are still unknown, that the profession has been compelled to stand aghast and wonder how long it would be until the human mind would be unable to comprehend medicine. Strange to say, however, there is finally coming out of all this mass of new knowledge and separate and distinct facts, a sense of unity which will, when worked out, simplify medicine.

The older medicine was a one-sided medicine. It dealt largely with observations which were made upon the patient. The knowledge of the disease was comparatively meager except in the manner in which it manifested itself clinically. The medicine which displaced it was also one-sided. It was natural that methods would go to the other extreme. With the development of microscopic pathology, bacteriology, and biochemistry the interest was shifted from the man to the bacteria which infected him and the manner in which his tissues changed under the influence of disease processes. The interest was shifted from the human being to the laboratory.

This laboratory era in medicine has been characterized by intensive study in limited fields of

specialization, and has resulted in a rapid systematization of discovered facts. Men have devoted months, years, even many years, to the study of single systems of the body, single organs, or single problems. This has resulted in the discovery of many independent facts which have enriched the knowledge of the subject under investigation. The segregation of these facts has resulted in building up many independent specialties.

This is where medicine finds itself today. While there is still much to discover, the fundamental branches for the most part are fairly well understood. A sufficient number of the fundamental facts of anatomy, pathology, bacteriology, serology, biochemistry, and physiology are established on a secure foundation to afford a safe working basis. The body has been divided up into many parts, and the diseases which affect each part have been constituted the subject of special study by men who are known as specialists in that line; even methods of examination have constituted specialties. This specialization has been carried to such extremes that some one has facetiously remarked that the only structure left to internal medicine is the umbilicus; and another suggests that we may expect to see rhinology divided so as to have specialists for the right nostril. But is specialization the end to be desired? Has our study been broadly directed? Can medicine render the best service to the public on this basis? Assuredly it can not. Medicine is becoming divided into illogical specialties. There is a chasm between the specialties and general medicine and between the physician and the patient. He has been studying his specialty so earnestly that he has often failed to realize its relationship to medicine as a whole, and has centered his thoughts on the disease and disease processes with such earnestness that he has failed to give due attention to the patient.

Laboratory versus Clinical Methods

The medicine which is dawning today will correct this evil. Clinical observation will once more be encouraged and prized. A clinical observation which recognizes a clinical reaction and shows the manner in which a disease process produces it is equal in value to the reaction shown by the microscope and in the test tube; and will be so recognized. In order to make progress in the study of the individual, the same preparedness for study and the same earnestness must be shown and the same desire for truth be manifested as has characterized the work of laboratory investigators. The knowledge that we now possess of laboratory methods, and the facts which have been revealed by them have resulted from days and years of study of hundreds and thousands of workers. If an equal number of efficiently trained clinical observers, fired by an equal zeal for facts, were to begin to develop those facts in medicine which particularly pertain to the patient and the manner in which he reacts to disease, we would after a few years have a very different understanding of our patient from that which we have today. The criticism is made, not without some degree of justice, that the laboratory takes the keenest and most scientific minds and leaves the rest to practise clinical medicine. Is it any wonder, then, that clinical observation lags, especially when we couple with this the body and soul wearying aspects of practice? The human body is also a laboratory, and trained men must discover its important reactions.

Pathologic anatomy results in disturbed function or pathologic physiology. Therefore it behooves clinicians to familiarize themselves with normal physiology, that they may recognize the pathologic changes which are induced by disease. It is highly desirable that endowed hospitals for the study of the patient be established, in which the reaction of the patient toward the disease process be thoroughly investigated.

If one would understand a disease he should know the manner in which the body reacts toward it through the nervous, the chemical or endocrine, the physical, and the psychical systems. For example: It is not sufficient to know the morphology, the chemical constituents, and the laws of growth governing the tubercle bacilli in the tissues of man; nor to understand the histology and pathologic changes which take place in the tubercle; nor to recognize the symptoms which result from the presence of the bacillus in the body and to be able to relieve those symptoms. If we are fully to comprehend the disease, tuberculosis, we must be able to explain how the patient suffering from tuberculosis reacts through his nervous, endocrine, physical, and psychical systems towards the infection. It is desirable to know how this and that symptom or syndrome is produced. In order to be able to appreciate and explain these reactions, a more accurate knowledge of normal and pathologic physiology and a more painstaking and more accurate observation of the patient is necessary. It is necessary that our physiologists and clinicians be closer together. Physiologists should be clinicians who are capable of making accurate clinical observations; and clinicians should be grounded in physiology and appreciate that the picture of clinical disease is a picture of disturbed physiologic equilibrium, or pathologic physiology.

The various organs and systems of the body are

so intimately bound together that their actions and reactions are so intricately correlated that no organ can be studied or considered except in its relationship to other organs and the body as a whole. The body is a unit, and a study of the clinical manifestations of any particular disease of any particular organ is a study of the manner in which that disease disturbs the functions: (1) of the organ in which it is located; (2) other organs and structures aside from that in which it is located; and (3) the physiologic mechanism as a whole.

The conception of the unity of the human body shows that the attempt to divide medicine into specialties of this and that organ is one of the fallacies of the age. It is a weakness that must be corrected. If you will pardon me for being so bold, I will say that specialization, in spite of the great service which it has rendered both to medical science and the public, must be looked upon as an evil, though a necessary one during the developmental period of modern medicine. The medical progress of the past three or four decades has been greater than in all preceding centuries. This progress has been made possible only by men limiting their study to one subject, and then pursuing it incessantly. The study of pathology, bacteriology, serology, biochemistry, and physiology has each advanced in this way. The vastness of the field was early recognized and the impossibility of one doing research work in many lines of the fundamental sciences was considered as self-evident.

The clinician, recognizing the great number of new discoveries which were being announced from laboratories and other sources of investigation, and feeling his inability to apply them to the broad field of medicine as a whole, created the clinical specialties. While this specialization and intense study of individual organs and systems led to a rapid application of discovered facts in the study of individual diseases and individual specialties, it also emphasized more and more to the broad-minded investigator that all diseases, no matter what their nature, disturb the physiologic equilibrium of other organs aside from the one in which they are located, and of the entire body; and consequently must be looked upon as belonging to a medicine which looks upon the body as a harmonious whole—general medicine.

It must not be thought, however, that specialization has been in vain. It has not. It has developed a virile, efficient medicine in a comparatively short period of time. During this period it has been only through specialization that the best service could have been rendered to the public. As the specialties have developed more and more, however, they of themselves have demonstrated their own innate weakness and shown that their permanence, at least in their present form, is illogical and unnecessary. It would be foolish to attempt to predict how long specialization will last. It will last until the facts in each specialty are so well worked out and recognized that they may be given back to general medicine in a way that they may be readily comprehended and applied. In some specialties this will be longer than in others. In fact, it is probable that specialties in some lines will always be necessary; but I can not conceive of a future internal medicine which does not comprise diseases of the cardiovascular, renal, respiratory, and gastro-intestinal systems; diseases of metabolism; functional disturbance of the nervous and genito-urinary systems; diseases of the endocrine system; and all systemic infections wherever located, whether of an acute or chronic nature. Even surgery, which has so long been considered apart from medicine, will find its place as an intimate part of internal medicine. While it is probable that individual men will always show a preference for study of certain diseases, it will be necessary that this study be pursued from the standpoint of the internist. Every specialist should be first an internist, and thus learn to look at his subject as being a part of the greater field. This broad view is necessary if disease processes are to be considered in their true relationships and proportions.

There has been too much of a tendency for each specialist to look at the human machine from his own standpoint. Thus Morris has wittily said: "It has been my observation that if a patient visits a heart specialist and comes away without finding that there is something wrong with his heart, it is proof that the specialist is not at home." No specialist should consider a patient as his subject. There are disturbances in function in many organs and systems of most people, yet not of sufficient importance to be considered as clinical entities. It is the duty of the physician to weigh and to know the value of symptoms, and to disregard those which are unimportant. This has been one point on which specialism has been extremely weak. It has looked upon its own field with exaggerated importance, and failed too often in recognizing the broad relationship of the functions of each organ to the body as a whole.

Group Medicine

Just at this time the weakness of specialization is being recognized, either consciously or unconsciously; and, in an attempt to overcome it, there is a movement toward group medicine. If specialism is the last word in the development of

clinical medicine; if it is the desired end, then some such organization to overcome this inherent weakness of the system is necessary. But group medicine, too, has many inherent weaknesses; and its general application as a permanent workable institution for rendering efficient service to the sick is questioned.

The practice of medicine is based on the individual practitioner's knowledge and experience. He applies his practice according to that part of the medical knowledge and that part of the clinical art which he has been able to make his own. The application is personal. It is not that of a group; consequently, while theoretically the patient receives the benefit from a collective group of specialists, practically he falls far short of this. If the treatment of the case is guided by one physician, the treatment will depend on the conception that this physician has of the individual specialties in which clinical entities have been found, but there will be a unity in its application. If, on the other hand, several members of the group undertake the treatment of the same patient, confusion and misunderstanding are almost bound to arise. The patient is apt to be approached from as many different angles as there are specialists, and the treatment of the patient from the standpoint of the clinical art will vary with the different men. This not only makes for confusion and demoralization of the patient, but creates preference and stirs up jealousies which sooner or later disturb if they do not destroy the harmony of the organization. As long as human opinion depends upon experience and as long as human nature is as it is, it is doubtful whether group medicine will be a permanent institution capable of rendering a service which in any way compares with the best of the individual specialties which form the group. If it does not, it fails in its purpose.

The type of group medicine which has the least inherent weakness is that in which some very capable internist gathers about him a group of associates who are able to give him a correct report on those phases of the case which are purely impersonal, while he himself attends to the personal phases and gives the opinion and directs the treatment. Another type which often makes for good service is that in which one strong, dominant character gathers about him men whom he can direct and control.

That highly trained and eminently successful men will as a general thing voluntarily associate themselves together in order to be able to assure the best services to their patients is hardly probable. The all important factor in the success of group medicine is the head or dominant character. He should be preferably an internist, of splendid training, wide experience, and possessed of broad-mindedness. All groups so dominated should become successful and should be able to render service more efficient than that usually given.

The Practitioner of General Medicine

I have faith in the final construction of a unified medicine in which the facts developed in all lines of special study shall be utilized, and so put together as to simplify rather than confuse. Specialism, with its tendency to disorganization, and group medicine, with its attempt to overcome specialism's weaknesses, will be looked upon only as steps in progress. The permanent structure of efficient modern clinical medicine can not be erected, however, as long as there shall exist many specialties which are considered as entities. It is only by their merging into the whole that unity can be maintained, and the most efficient service be given.

Even should future experience show that it is through specialism that medicine can render her best service, it will be through specialists who are primarily and fundamentally internists. With greater knowledge of the workings of the human body, particularly of the manner in which the action of its various parts are correlated and integrated through its nervous and chemical controls, will come an appreciation of its unity; and just as it was natural during the early developmental period of modern medicine to emphasize specialism, so with a full knowledge will it be equally natural to emphasize the importance of general or internal medicine. The importance of the whole will assume its true relationship when compared with its parts. Preparatory to and for the purpose of hastening this end, those who are interested in this movement should consult together and devise means for furthering the interest of general medicine.

"The physician henceforth becomes not merely a person who stands ready to treat disease when the accidental and incalculable forces of custom, hearsay, and natural propinquity bring the patient to him. He becomes now a person who actively wars against disease, who searches it out wherever it may be found. Thus he approaches for the first time the possibility of truly preventive action, the possibility of killing disease in its infancy or preventing its birth. For it is well known that preventive action is well-night impossible if we are forced or accustomed to wait until the disease has made such progress that the patient himself is aware of it and forced by its ravages to ask medical aid."—Richard C. Cabot,—"Social Work."

SOCIAL WORKERS FOR MENTAL HYGIENE

By HARRY C. SOLOMON, M.D., Massachusetts State Psychiatric Institute, Boston, Mass.

IT is a very simple matter to care for a patient in a hospital. The outlining of treatment is all that is required of the physician, and his orders are carried out without more ado. Thus, a diabetic may be ordered diet number two; he gets diet number two without any more thought from the physician about the matter. Or, if it be a tuberculous patient, the physician gives certain general and special orders,—then his job is done and he is sure that his orders will be carried out. The reason for this relative simplicity is, of course, "organization" and "system."

The treatment is much more complicated when the patient cannot be readily hospitalized. The physician ordinarily lacks organization and system in care for his private patients; and until very recently the dispensary physician was even worse off than the private physician, being able to give a relatively short time to the individual patient and often having to deal with patients of an inferior intelligence and insufficient means. Orders were likely to go amiss, and advice not to be followed. Often the orders given could not be carried out by the patient, either because he did not have the means at his disposal, or else because he did not know how to carry out complicated orders. To improve this state of affairs, to deal in possibilities instead of unattained desires, medical social work materialized, and, like all hardy new growths, it flourished, bringing social service technic into the medical clinic, and aiding the patient and his family in many ways new to the physician. It is now a part of the clinic and has become practically indispensable.

Even more important than medicine, which often deals with mechanical or functional disorders, or with defects of single organs, is the psychiatrist's objective of a fully integrated personality adapted to its environment.

Physicians must evaluate the findings of the psychological as well as the physical laboratory. He needs to consider past as well as present reactions, for no diagnosis is complete which does not consider the whole organism and its characteristic attitudes.

In the achievement of such an objective, medical science must use the knowledge of such other sciences as psychology and sociology, in an intelligent program for the restoration of the maladjustments caused by or producing illness.

The Art and Science of Mental Health

But all this is old, established, and accepted. Today the general hospital and dispensary consider the social service almost as indispensable as the laboratory. The object of this review is to focus attention on another field of medical social work, not so old, possibly not yet so firmly established, and not so exuberant—namely, psychiatric social work. If not so old as general medical social work, it has the advantage of all youthful things, the promise of rapid growth, virility, and optimism.

Psychiatry deals with cases of insanity, but today it is far more inclusive than this. It may better be called the "art and science of mental health." Its domain takes in the neuroses or borderline states; conduct disorder, with its resultant legal entanglements; and child study, with particular relation to the unusual child. Its aims reach more and more into the community and away from the institutional cases of former days. In this field, again, one finds that the care of a patient in a hospital is a comparatively simple matter. A patient who is committed to an institution for custody because he is suffering from mental disease is, as long as he remains in the hospital, a simple problem as far as the doctors and the hospital are concerned; but in relation to such a patient psychiatry has a bigger and broader purpose than merely caring for him during his acute or chronic sickness. The study and care of the patient begins, of course, long before he reaches the state of institutional care. There is a longer or shorter period during which, as a member of the community, he is in a sense to be considered an out-patient; and those who recover must take their places again in the community to receive supervision and medical care. The extramural care of mental and nervous patients is far more difficult than the intramural care; and, just as in the case of the general hospital patient, social service has grown up as an important institution, so in relation to mental cases a similar organization has been developed. It is probably more important to have social assistance for the handling of a psychiatric problem than in any other medical contingency.

Multiple Adjustments Involved

Let us consider one of the most simple cases,—a married male adult without children. He first comes to the attention of the physicians in a state of excitement. This is so apparent that it is at once obvious that custody is demanded. As he is without means, the state defrays the expense of his care; but his wife is left in a condition which makes it necessary for her to earn her own living. Assistance and guidance will put her in a position to care for herself. Obviously, a physician is not in a position to aid her in this situation, and here a problem arises that can be turned over to the social service for solution. The importance of this matter from the standpoint of the patient becomes apparent at the time when the patient is recovered to a sufficient degree to be discharged from the institution. The hard problem for this patient then arises, when he goes back into a community somewhat suspicious of him, because he has been adjudged insane. A new adjustment is necessary, and the social worker who has been in touch with the situation during this period can again come forward and help in obtaining a position for him, assist the wife in re-establishing a home, and offer a bulwark of support which may be the most important bit of therapy that the patient can possibly receive. He has someone to rely upon and to aid him; a contact between the institution and the patient is kept alive through the mediation of the social service department, and visits for further medical advice are readily made possible.

As stated, this is one of the simplest contingencies. As the cases become more and more complicated, the social conditions more intricate, the need and value of the social worker becomes more and more apparent. As a matter of fact, in the present state of psychiatry the environmental factors are in the majority of cases the ones that are most easily affected of all the etiological factors. They play a very important part in prophylaxis and treatment. For proper handling there must be someone who

understands the technic of environment and the methods by which it may be changed or corrected. Certainly every psychiatrist should be, and is, able to see the need of changes in environment and to outline what the conditions should be; but it is a very rare exception when he is able actually to control the situation and change the environment. This requires a technic not medical but social in type. This is particularly true in mild nervous and mental disorders and those whose care is extramural. In such cases the difference between home conflicts, uncongenial surroundings, unhealthy environment, nerve racking work, and a peaceful home life, happy and healthful surroundings, and congenial work may supply the difference between mental health and mental disease. As already indicated, the physician may be in a position to diagnose the difficulty, but he is rarely in a position to to correct it. The special knowledge and training of the social worker should be such that this solution may be attained.

As delinquency and crime come more and more to be recognized as depending upon certain mental defects or anomalies, their correction comes more and more into the line of physhiatric work. In this field, again, the psychiatrist's chief work is the diagnosis and outlining of treatment. A large part of this treatment is social in character and its execution will depend upon the abilities of the social worker to whom the carrying out of the treatment may be detailed.

Sometimes in a spirit of raillery the psychiatrist is characterized as "a sublimated social worker." Leaving the sarcastic implications aside, it is true that the social aspect of many psychiatric cases is dominant; but the word "sublimation" refers to the fact that a psychiatrist is not a social worker in the ordinary sense of the word; he must have outside assistance, and this outside assistance must be given by a trained psychiatric social worker. We must grant, then, that a social worker is an essential component of any successful psychiatric organization. This is particularly true in those psychiatric organizations caring for extramural cases, but there can be no truly intramural care alone for a patient, because he is a member of the community either before he is committed to the institution or after he leaves it, and even during his stay there are many social problems arising in the case, the proper handling of which will shorten his stay in the institution and, if he is a recoverable case, hasten his recovery.

By far the largest field of psychiatry is that of mental hygiene; or, at least, the handling of cases which are not institutional cases, and here the need of manipulating the environment is particularly essential. It thus becomes evident that social work is essential in psychiatric situations; and if it is to be done at all it should be done on a high plane. The psychiatric social worker must be a person thoroughly trained in the technic of social work. Such training means more than mere case work, although this is an essential for all good psychiatric social work. In addition, the psychiatric social worker should have a knowledge of the underlying economic and social principles of modern society. For dealing with the abnormal or difficult personality a certain training in psychology and abnormal psychology is essential. One must thoroughly understand the types of personality with which one deals. One ordinarily accepts as a premise that any social worker has an understanding of personality as an inborn gift. This may or may not be so, but certainly the more insight into personality the worker has the greater will be her success.

While everyone, in his ordinary experience of life, learns much about the personalities of the individuals with whom he is in contact, certain special knowledge will be necessary for a person dealing with the anomalous or abnormal personalities. A normally astute individual will, of course, learn a good deal in this matter by experience. But this may in no way be considered equivalent to a fundamental training. We may then assume that psychiatric social work is a necessity; and, that to do it successfully, proper training is of the utmost importance. This training should be both theoretical and practical. On the theoretical side a knowledge of sociology, psychology, and the elements of psychiatry is needed. On the practical side, the usual training in social case work and special training in the handling of mental disease cases, delinquency, and the like, must be obtained. The proper training of a psychiatric social worker will include work of a collegiate character, and practical experience in social work and psychiatric social work. With a recognition of these factors a good beginning in this type of training has been made by the Smith College Training School for Social Work, which offers both the collegiate training and the practical work, and presages a good outlook for the future.

The Need Is Urgent

There has been a growing recognition of the need of psychiatric social work throughout the country. Whereas eight to ten years ago the number of hospitals supplied with such service could readily be counted on the fingers of one hand, now hospitals throughout the country have instituted this service. The demand created by this rapid installment of psychiatric social service departments has undoubtedly led to a great shortage of adequate material, as can be vouched for by the experience of the Red Cross in filling the positions in the newly organized Public Health Hospitals throughout the country.

The Red Cross is now making a vigorous campaign to recruit one hundred social workers already trained in case work to be prepared through summer courses in social psychiatry at the Smith College Training School, New York School of Social Work, and Chicago School of Civics, to fill the immediate pressing demand for psychiatric social workers; and at the same time is urging college graduates to enter the regular training courses in these schools now, in order to be ready for positions a year later, when the demand for trained workers is expected to be even greater. The Bureau of Medical Social Work of the Red Cross in Washington is offering scholarships to trained social workers to take the summer courses. A few scholarships for the training course in the Smith College Training School for Social Work may be available for college graduates.

The difficulty in obtaining adequately trained workers has also been felt and commented on by the heads of numerous hospitals who have attempted to install a proper system of social service. If we are to continue our advance in psychiatry, it will be necessary to stimulate the training of the psychiatric social worker; and the type required is preferably the college trained person who has had special training somewhat as outlined here. I believe it behooves all who are interested in psychiatry to stimulate interest in this work by drawing the attention of qualified persons to this profession. It is in this spirit that this paper is written.

"Consciousness of the need of adjustment to surrounding conditions and events is the *raison d'etre* of thought." —Ordway Tead.

LAW FOR THE DOCTOR*

By LESLIE CHILDS, Attorney at Law, Indianapolis, Ind.

Liability of a Physician for Selling Drugs Without a Prescription

An interesting case, relative to the liability of a physician for selling drugs without a prescription, under an act requiring the issuing of a prescription before certain drugs could be lawfully sold, is reported under the title of Niswonger *vs.* State, in 179 Ind. 653. The case arose in Indiana, under the Drug Act of 1911 of that state, the facts being as follows:

Henry W. Niswonger was a licensed physician and pharmacist located in Allen county, Indiana. He was accused of selling one-eighth of an ounce of cocain to one John Burton for the price of one dollar. The said sale was alleged to have been made without the written prescription of any duly licensed physician, veterinarian, or dentist, as required by the Indiana Drug Act.

The Drug Act, under which the prosecution was made, provides, among other things, as follows: "That it shall be unlawful for any druggist or any other person to retail, sell, or barter or give away any cocain, . . . except upon the written prescription of a duly registered physician, licensed veterinarian, or licensed dentist. . . .

From the report it appears that the defendant's main contention was that as a physician he had the right to furnish his patients medicine without writing a prescription. And, that if, in his opinion, cocoain was required, he could lawfully sell it without complying with the provisions of the Drug Act quoted from above.

The case was tried in the Circuit Court for Allen County, without the intervention of a jury, and resulted in the conviction of the defendant. From this judgment an appeal was prosecuted to the Supreme Court. In passing on the points raised the latter court in part said.

"The statute in question prohibits the sale, barter, or giving away of cocain except under certain conditions, and it was not intended to exempt licensed physicians from its terms. There is nothing in the Act which will authorize a physician to operate a drug store and, as such druggist, to sell cocain indiscriminately to any one applying therefor without having a written prescription as required by law. Such prescription is a prerequisite to any sale of either of the drugs mentioned in the statute, and must be retained on file by the person making the sale." The Supreme Court thereupon affirmed the judgment of the lower court.

The holding may, upon first glance, appear to exalt the letter of the law at the expense of the spirit, but a slight examination of the subject quickly proves that this is not the case. The language of the Act is plain, clear, and concise, leaving no grounds whatever for an exception in favor of anyone. Had there been an intention on the part of the legislature to exempt physicians from the operation of the Act, it is reasonable to suppose it would have been expressed in the statute, as other exceptions were. Manifestly it was not within the province of the court to read such an exception into the Act, had it so desired.

Presumably, no offense would have been committed had the doctor taken the time to write a prescription for his customer before giving him the cocain, though this may well be doubted, unless the customer was in reality a patient and as such in need of cocain. Certainly if the customer was merely a buyer of cocain, as it seems from the report, the doctor would have violated, at least the spirit of the law, in selling it either with or without a prescription.

It is worthy of note that the decision in this case is in harmony with a like case which arose in Oregon under a similar statute, the latter case holding that the fact that the seller was a physician gave him no right to sell certain drugs—morphin in this instance—without a prescription, where the statue provided that they should only be sold on such a writing.

When it is also considered that the effect of permitting such an exception would tend to open the way, at least make it easy, for anyone possessed of a physician's license to engage in an illicit traffic with certain drugs, the soundness of the decision is further apparent.

*The thirteenth of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

CARDIAC AILMENTS A MOST PREVALENT CAUSE OF DEATH

Cardiac ailments are far more prevalent than is generally suspected, while ignorance of this fact is a matter of surprise, since the danger from this class of maladies is fully understood, according to a pamphlet issued by the Association for the Prevention and Relief of Heart Disease from their new headquarters, 325 East Fifty-seventh Street.

An official report of the health department the Association shows that 10,682 deaths in New York City alone in a single year were directly due to organic disease of the heart, while in the same period tuberculosis, in all its forms, caused 9,622 deaths and cancer but 4,702.

The Association declares that not less than 25,000 public school pupils of the city have permanently damaged hearts while many more suffer from other diseases which are liable, unless controlled, to bring about the same result. Adults suffer for years from heart disease, mistaking their symptoms for those of indigestion or other stomach troubles, and wonder why their sufferings do not yield to home remedies.

The Association in its pamphlet asserts that the prevention of heart disease presents both medical and social problems, but it urges the prompt removal of diseased tonsils and adenoids and the immediate care of decayed teeth, as the most effective preventive against infection with rheumatism, which is cited as an infectious disease most frequently affecting the heart.

Poisons of alcohol, tobacco, tea, and coffee are mentioned as "playing a definite rôle" in degenerate diseases of the heart.

The Association is now engaged in furthering the establishment of dispensary classes for workingmen with crippled hearts in the many city hospitals, and also seeks the opening of more convalescent homes to patients of milder type, and the founding of institutions for the permanent care of permanent invalids from the same cause.

Dr. Lewis A. Conner is president of the Association, and Ray Morris, the treasurer, while among the governors, who number many lay members, are Dr. Alexander Lambert, Dr. Haven Emerson, Dr. John W. Brannan, and Dr. S. Josephine Baker.

WALTER H. BROWN TO RED CROSS

Dr. Walter H. Brown has been appointed Associate Director of the Department of Health Service of the American Red Cross, with headquarters in Washington, D. C.

Dr. Brown is a graduate of Jefferson Medical College (1906) and of the School for Health Officers of the Massachusetts Institute of Technology and Harvard College (1915). For the last three years he has been Health Officer of Bridgeport, Conn., a member of the Connecticut State Board of Health, and lecturer at Yale University.

INBREEDING AND OUTBREEDING. Their Genetic and Sociological Significance. By Edward M. East, Ph.D., Harvard University, Bussey Institutions, and Donald F. Jones, Sc.D., Connecticut Agricultural Experiment Station.[1]

Inbreeding and Outbreeding; Their Genetic and Sociological Significance is one of the "Monographs on Experimental Biology" now being published under the editorial direction of Dr. Jacques Loeb. In it the authors discuss the much disputed question as to the effect of inbreeding and outbreeding. In a series of introductory chapters they examine the mechanism of reproduction, the mechanism of inheritance, and mathematical considerations. They then come to their actual theme. To know the facts as to the effects of in- and out-breeding, an immense number of carefully controlled experiments must be carried through a long series of generations. The older observations have little value as they fail to meet the rigid demands of present day science.

As regards inbreeding, the recent experiments upon mammals, insects, and hermaphrodite plants are carefully detailed. The most complete are Castle's studies upon *drosophila* carried through fifty-nine generations and the long series of experiments on maize made by Shull, East, and Jones. Interbreeding is undoubtedly, at first, attended with harmful results. To what degree these are actually due to the interbreeding, and not to other causes, is important to determine. After some generations the disadvantages may disappear and health strains of markedly true type result. "Inbreeding has but one demonstrable effect on organisms subjected to its action—the isolation of homozygous types. The diversity of the resulting types depends directly upon number of heterozygous hereditary factors present in the individuals with which the progress is begun."

Outbreeding is next carefully examined. There is no question that crossing between varieties and even between species gives immediate rise to individuals of much vigor and frequently desirable qualities, although often sterile. The facts of hybrid vigor and its causes are investigated at length. The sterility that accompanies inbreeding and that which accompanies outbreeding are quite different and must be clearly recognized as such. Outbreeding, within limits, is clearly advantageous. The deductions made are now applied to the questions of evolution and the betterment of animals and plants in domestication. Neither inbreeding nor outbreeding is to be neglected; they may well be combined. Analyze the material by systematic and vigorous interbreeding; then cross the different constant types and test one combination after another until a real improvement be effected.

In two final chapters the matter of inbreeding and outbreeding as related to man is considered. Here, again, inbreeding is not in itself harmful; nor is outbreeding necessarily advantageous. In one chapter the question of family purity and desirable selection to that end is considered; in the other, the problem of intermingling of races is examined. By inbreeding desirable types may be isolated; by judicious crossing of such types desired vigor and a useful combination or compensation of characters may be brought about.

FREDERICK STARR.

THE HEALTH OFFICER. By Frank Overton, A.M., M.D., D.P.H., sanitary supervisor, New York State Department of Health, and Willard J. Denno, A.B., M.D., D.P.H., medical director of the Standard Oil Company., formerly secretary New York State Department of Health.[2]

This excellent handbook for health officers is sure to run through many editions. It is for this reason that a few minor criticisms are ventured upon in this brief review, which, because of its conciseness, might well be limited to extolling the numerous merits of the work. By conscientious labor the authors have produced a remarkable *vade mecum* for the health officer; but it is to be regretted that the numerous illustrations of procedures and legislation are limited almost exclusively to the State of New York. Descriptions of organization and achievements of health work in other states and municipalities would have added to the value of the book. The enlargement of certain sections would have been advantageous; for example, more comprehensive material dealing with insect borne diseases would have made it of greater service to health officers in localities where these diseases are prevalent. In discussing the relationship of the health officer to the public and to physicians it would have been of advantage to discuss also his relation to voluntary public health agencies. In this connection, the modern movement toward health centers might have been mentioned; and a discussion of principles of efficiency in administration, as well as of budget making, would have been of value. The chapter on epidemiology should be materially strengthened and examples of epidemiological studies of note cited. Either in this chapter or in connection with the section on vital statistics the principles of the statistical theory of correlation should have been, if not discussed, at least pointed out; likewise, the use of the graphic method should have been illustrated.

The book would be strengthened by the addition of a chapter dealing with the organization and management of a hospital for contagious diseases.

Throughout the work, the adjective *un*sanitary is used instead of *in*sanitary.

With these and other changes and additions incorporated this work is destined to occupy the place of a standard reference and guide for the health officer. The authors are to be congratulated on the successful outcome of their effort.

AMERICA'S MOST FAMOUS DESSERT
JELL-O
TRADE-MARK REG. U.S. PAT. OFF.
A MIXTURE
SPECIAL PACKAGE
NET WEIGHT 28 OZS
MAKES FOUR QUARTS
RASPBERRY
PURE FRUIT FLAVOR
VEGETABLE COLOR
This package makes four quarts of Jell-O. Serves forty to fifty persons according to size of portion.
Dissolve the contents of the package in four quarts of boiling water and set in a cold place to harden.
If only part of the contents is to be made up at one time, allow exactly one pint of boiling water for each 3½ ounces (100 grams) of powder.
Further directions of great importance are given on each of the two side panels of this package. Be sure to read them.
THE GENESEE PURE FOOD COMPANY
LE ROY, N.Y.

The Special Size for Hospitals

One gallon instead of one pint of Jell-O is made up from the new Special Package of Jell-O, saving nine-tenths of the time required for opening and emptying the common small size.

This change eliminates the last remaining bit of real work connected with the preparation of Jell-O dishes.

Among the dishes which the nurse likes to prepare are the refreshing and attractive salads of which the foundation is Jell-O. These are made by adding to the Jell-O chopped celery and bits of fruit and nutmeats. They are moulded in teacups or little moulds and each is turned out on a lettuce leaf.

As Jell-O contains sugar and the other ingredients that would have to be added if plain gelatine were used, there is a great saving of time and labor, and the result is always satisfactory. The nurse who uses Jell-O for her dainty dishes is never obliged to depend upon luck.

Jell-O is made in six pure fruit flavors: Strawberry, Raspberry, Lemon, Orange, Cherry, Chocolate.

The new Special Package for hospital use contains enough Jell-O to make four quarts of jelly as against one pint of the regular small size.

THE GENESEE PURE FOOD COMPANY
Le Roy, N. Y., and Bridgeburg, Ont.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRITPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from page 468)

PSYCHOLOGY FROM THE STANDPOINT OF A BEHAVIORIST. By John B. Watson, professor of psychology, the Johns Hopkins University.[3]

The materials of every day contact form the proper against the mysterious explanations offered by earlier psychologists he discards all traditional classifications. basis for psychologic research, according to Watson; and in his determination to direct study toward facts, as Practically the only terms he has used in this thesis are thinking and memory, and these are carefully re-defined.

The chapters dealing with the physiologic basis of the necessary part activities are partieularly valuable and his treatise on the functions of the endocrine glands constitutes an admirable summary and correlation of the recent work in this field.

After delimiting the rôle played by the emotions and instinct, which he designates as "patern reaction," he traces the increasingly complex adaptations through systems of explicit bodily habits to complete integration.

The chapters on the completely integrated organism have to do with the process of learning and with concrete matters for future study. All of the conclusions stated have been worked out in objective or behavioristic terms. His method puts aside presuppositions and the results of his psychologic experimentation are immediately practicable. The work is perhaps the most important contribution to psychology in a generation.

INFECTION, IMMUNITY AND SPECIFIC THERAPY, with Special Reference to Immunologic Technic. By John A. Kolmer, M.D., Dr. P.H., M.Sc., assistant professor of experimental pathology, University of Pennsylvania. With an introduction by Allen J. Smith, M.D., Sc.D.. LL.D., professor of pathology, University of Pennsylvania.[4]

The second edition is most welcome to those who know the excellent qualities of the first edition. It is a work as valuable to the practising physician as to the laboratory worker; and no modern laboratory dealing with medical diagnosis, serology, and biological chemistry can afford to be without a copy on the work bench.

The second edition contains a digest of all the important work on this subject since the appearance of the first edition. There is no other book in English which gives to the student such a clear presentation of the theory of modern serological problems and their application to medical diagnosis.

ELEMENTARY BACTERIOLOGY AND PROTOZOOLOGY. For the Use of Nurses. By Herbert Fox, M.D., director of the William Pepper Laboratory of Clinical Medicine in the University of Pennsylvania, Pathologist to the Zoological Society of Philadelphia, etc.; Major, M.C., U.S.A.[5]

This is really not a bacteriology for nurses, but rather an abbreviated textbook of the elements of bacteriology. Neither the subjects chosen for discussion nor the manner of their exposition would seem to meet the more usual and urgent problems of the nurse. Some understanding by the nurse of the processes of immunity is most desirable, but the author essays the impossible in attempting to explain the entire subject in five pages. Disinfection and sterilization, matters of the utmost practical importance, deserve far more detailed treatment than has been given them.

HEBE

All the food value of skimmed milk plus the food value of scientifically refined vegetable fat

Used in Cooking it Enriches Food, Improves Palatability and Helps to Balance the Diet

HEBE is a scientific emulsion of pure skimmed milk and carefully processed cocoanut fat. It is a nutritious, healthful, economical food product to be used as a liquid ingredient in cooking.

HEBE contains all the nutritive elements of skimmed milk plus finely divided fat. In this form the vegetable fat is readily assimilated making HEBE an easily digestible food. **Used in cooking and baking, it enriches foods, improves palatability and helps to balance the diet.**

In the production of HEBE complete sanitation is the first concern. Extreme care is exercised throughout the process from the refining and testing of the ingredients to the final sterilization of the finished product in the hermetically sealed cans.

Physicians, health officers, dietitians, public health and industrial nurses should be interested in HEBE, not only because of its dietetic value, but also because of its importance as an economic addition to the country's food supply. HEBE reclaims for use as human food, skimmed milk, billions of pounds of which are used in this country every year for stock feed.

Skimmed milk is highly nutritious and should be utilized for human food. Enriched with vegetable fat, as it is in HEBE, it makes a desirable, economical and healthful food product for cooking purposes.

HEBE is properly labeled and sold for just what it is—"A Compound of Evaporated Skimmed Milk and Vegetable Fat." Directions for its use are printed plainly on the label. It is not intended to be used in place of milk for infant feeding. We will mail on request a booklet giving the complete facts about the dietetic and economic value of HEBE. Address 2622 Consumers Building, Chicago.

PUBLIC HEALTH AT NORFOLK, VA.

The Public Health Department of Norfolk, Va., under the direction of Dr. P. S. Schenk, proposes a progressive and ideal health center which will bring into one group the children's court and domestic relations court, a general medical building, the prenatal building, the detention building, the emergency hospital building, and an administration building which will hold the drug dispensary, the city laboratories, as well as the executive offices. The unifying of all the work of the department and its proper housing constitute a very progressive policy.

HOSPITAL STANDARDIZATION

Two events of interest in the progress of hospital standardization are reported in the current issue of *Surgery, Gynecology, and Obstetrics*: The gift from the Carnegie Corporation of $75,000 to be used for hospital standardization; and the official adoption of the standardization plan by the hospitals of New York City under the direction of the Department of Public Charities. The constructive program looking toward standardization is outlined chronologically. The Carnegie gift means encouraging approval as well as financial aid in the achievement of the work. Its adoption by the hospitals of New York City will insure on a large scale the demonstration of the advantages of good equipment, dependable management, adequate records, and the provision for regular and fearless review of what is actually accomplished for the right care of patients.

MEDICAL EXAMINERS INCORPORATE

Senate Bill No. 3959 has been introduced by Senator Kellogg to incorporate the National Board of Medical Examiners of the United States of America. It provides that Rear Admiral William C. Braisted, U. S. N.; Major General Merritte W. Ireland, U. S. A.; Surgeon General Rupert Blue, U.S.P.H.S.; Admiral Edward R. Stitt, U. S. N.; Colonel Louis A. LaGarde, M.C., U. S. A., retired; Assistant Surgeon General William Colby Rucker, U.S. P.H.S.; and Drs. Herbert Harlan, Baltimore; Isadore Dyer, New Orleans; Victor C. Vaughan, Ann Arbor, Michigan.; Walter L. Bierring, Des Moines, Ia., and such other persons as may be chosen who are members of the National Board of Medical Examiners, as unincorporated, non-profit association, known as the National Board of Medical Examiners, and their successors, are hereby created and declared to be a body corporate.

COST OF RECREATION

The following figures are given out by the Playground and Recreation Association of America in reporting recreational activities during 1919:

Seventeen cities report a total of $13,510,000, an amount which exceeds the 1918 figures by $13,441,073.14. Pittsburgh has issued $831,000 worth of bonds. Detroit's campaign for additional playground facilities resulted in an agreement to issue $10,000,000; Portland, Ore., issued $500,000 in bonds for this purpose; Indianapolis issued $87,000 in bonds.

The Playground and Recreation Association of America reports that four thousand playgrounds and recreation centers were maintained in 1919 under paid leadership. More than eight thousand men and women were employed by municipalities to direct these activities, and more are studying to develop the requirements along this line.

CHLORAZENE

THE DAKIN ANTISEPTIC

Ready for Use by Dissolving in Water

Chlorazene is the simplified Dakin antiseptic.

No laboratory apparatus nor involved and technical process is required for its use.

Chlorazene may be used in twice the strength of the sodium hypochlorite solutions without irritation.

Chlorazene is stable—it will keep indefinitely.

Irrigative solutions for use according to the Carrel-Dakin method may be prepared with Chlorazene promptly and economically.

Hospital Package No. 1 of Chlorazene Powder makes 4 gallons of 0.25 per cent solution and costs only 68 cents net.

Chlorazene Tablets have a wide range of usefulness in surgery and general practice. One tablet dissolved in one ounce of water makes a 1 per cent solution and is used for cuts and wounds, boils, carbuncles and ulcers and skin affections.

One tablet dissolved in 4 ounces of water (¼ per cent solution) is effective as a gargle, mouth wash and nasal douche. As a vaginal douche four tablets are used to a quart of water.

Food Flavor and the Mental Attitude

To every prescribed treatment for human ills should be added the element of contentment for the patient, for the very decided relationship between mental ease and physical responsiveness has long since been established.

It is apparent, then, that food, the very source of energy and repair of tissue, should be made as pleasing as possible for those who are physically subnormal, that the chain of healthful reactions—from mental to physical—may be complete.

SAUER'S
PURE FLAVORING EXTRACTS

make food especially satisfying to the taste. By their use the prescribed diet can be made to render its utmost benefits to the patient.

Various American and European Expositions have awarded seventeen highest awards to Sauer's Extracts for Purity, Strength and Flavor.

Sauer's is the largest selling brand in the United States.

PSYCHOLOGIC TESTS FOR CHAUFFEURS

New Jersey has awakened to the need of psychology tests for would-be chauffeurs. Commissioner William L. Dill of Newark has discovered that many drivers in New Jersey are only seven years old mentally. Many applicants have licenses who are able to pass examination through coaching and drilling would by a psychological test be disclosed as totally unfit to drive automobiles through the streets.

NEW SYSTEM OF VOCATIONAL GUIDANCE

Dartmouth College proposes to give college boys a knowledge of their patitude. Psychological aids will determine their types and their general grades of intelligence. A system of condensed records will follow their progress and note variations of affirmations of the traits identified. In this manner it will in many instances be possible to determine very easily the line of work that offers them the best chance of success.

As the work develops it will become possible to give the employer who is in search of recruits from the college complete and accurate information of candidates for positions. Such vocational guidance differs from vocational training, and the system obviously enables the application of physical and mental corrections and stimuli as needed.

TUBERCULOSIS AMONG WOMEN WORKERS

Recent statistics seem to indicate that the increased death rate from tuberculosis among white females between the ages of 25 and 55 is due in no small degree to the large and sudden influx of millions of women into industrial pursuits. According to the National Tuberculosis Association, the women of America are beginning to pay the bill for their entrance into industry. It seems unreasonable to expect that some three million women who during the war took up new and vigorous forms of industrial life should not suffer from increased incidence of tuberculosis from the sapped vitality and lowered resistance that such a life entails. The figures of the life insurance companies seem to indicate that men have been able to stand the strain of war work better than women.

MALARIA IN SOUTHERN ITALY

Signor Nitti estimates that there are at least two million hectares of land in southern Italy that are not cultivated on account of malaria. He computes the annual cases of malaria at upward of two million, with 15,000 deaths. The mortality is not extreme, but the consequences in enfeeblement and entailed disease are beyond computation. For every one hundred thousand inhabitants, the annual deaths for malaria are: In Liguria, 1; Piedmont, 3; Lombardy, 4; Veneto, 7; Sicily, 78; Calabria, 83; Apulia, 120; Basilicata, 124; Sardinia, 169.

FREE CLINICS ON TRACHOMA

In Kentucky regions trachoma has been very prevalent and the spread of contagion has been favored by the complete ignorance of the people as to the extent of the disease and its serious results if not checked. Red Cross workers in the district have been instrumental in securing the service of Dr. McMullen of the United States Public Health Service as well as a specialist from Baltimore and nurses who instituted free examination and treatment. In addition to the Kentucky work, Red Cross cooperation In addition to Kentucky, Red Cross cooperation has been effective in trachoma work in Ohio and North Dakota.

Sound, Restful Sleep—as Essential to Individual Health and Efficiency as Food and Drink

GET a *good sound sleep* every night —every nerve, every muscle relaxed—and Nature will fill your body with new energy, and wake you up fit and fine.

Every muscle relaxed! No one can sleep perfectly with nerves on edge or muscles tense.

This is the reason why doctors are urging *Twin Beds*—so one sleeper will not disturb the other, or communicate a cold or other infection.

The reason, too, why you should be sure your bed is *noiseless*. Just the little creak of a wooden bed, or the rattle of an ordinary metal bed, is enough to put the nerves on edge, even though it may not actually wake you up.

* * *

The truly *noiseless* Bed is the Simmons Metal Bed—*built for sleep.*

Just as the truly *sleep-inducing* Spring is a Simmons Spring—a fine resilient spring that invites the body to *relax.*

Years ago Simmons Company established the principle of Beds and Springs *built for sleep.*

It is today the largest maker of fine Metal Beds and Springs in the world.

It is a specialist in *Twin Beds*—a pioneer in that fine modern principle of a separate bed for each sleeper.

* * *

Simmons Metal Beds and Springs are the most sought after sleeping equipment in leading stores all over the country.

The prices are little if any higher than for ordinary beds.

And when you are selecting your Simmons Beds with an eye to their appearance in the room, you will see that Simmons has for the first time established *beautiful and authoritative design* in Metal Beds.

Sleep is a big subject! Write us for the brochure, "What Leading Medical Journals and Health Magazines Say about Separate Beds and Sound Sleep."

BULLETIN ON WAR RISK INSURANCE

The Bureau of War Risk Insurance has recently issued a bulletin as a guide to injured men stating that

"No compensation is payable unless the disability or death can be traced to an injury or a disease incurred in the service.

"Many persons, however, have received injuries or contracted disease in the service and the ill effects thereof do not appear until some time after their discharge or resignation. If the disability resulting from the injury or disease contracted in the service does not occur before one year after discharge or resignation you may be unable to obtain compensation, for the law provides that when such disability or death occurs as shown by the medical evidence after one year after your discharge, a certificate of injury must have been obtained from the Director of the Bureau, within the year from the date of your discharge in order that the government may pay you, or your dependents.

"If you were injured or contracted disease while in the service, even though the injury or disease was of a minor character, be sure to apply for a certificate of injury before one year after the date of your discharge or resignation in order to protect yourself and your dependents. Act now."

EDUCATION FOR MOTHERHOOD

The next step in the campaign for infant welfare, according to Dr. Isaac W. Brewer, is the education of the women of the nation for motherhood. The trouble with welfare stations, he says, in the *Boston Medical and Surgical Journal* of March 11, is that few mothers apply to the station until the health of the child has already been injured. The ideal aimed at should be to make an efficient course on the care of the child an integral part of the education of every woman. It is doubtful if necessary instruction can be added to the school course for some years to come. To supply the need, the various infant welfare stations should become teaching centers by receiving a limited number of young women as helpers who, while helping, would gain a practical knowledge of the care of a child. The infant mortality in this country is greatly in excess of what it should be in an enlightened community where proper educational and preventive measures obtain.

HYGIENE FOR WORKERS

It has been demonstrated that careful medical supervision in industry reduces absenteeism and turn-over according to Dr. Cecil K. Drinker of the Harvard Medical School, who stated recently:

"It is impossible to obtain such benefits without aiding equally and materially both the employer and the employee, and it is to this end that industrial medicine must be organized. If the return is one-sided, either for the employer or the employee, real success is not being obtained."

The growth of the practice of industrial medicine in the United States has been constant and rapid. At the present, approximately one thousand firms are known to be employing full-time or part-time physicians, and every day witnesses the institution of medical work in more and more factories. "That the health of the working population will eventually be both safeguarded and improved by such progress is very certain."

No Unbroken Food Cells

Steam-Exploded Wheat

Here is whole wheat, fitted, as never before, for easy, complete digestion.

The grains are steam-exploded —shot from guns. They get an hour of fearful heat—550 degrees. The moisture in each food cell is thus changed to steam.

When the guns are shot, that steam explodes. Each of the 125 million food cells is exploded separately. Thus every granule of the whole wheat is fitted to easily digest.

Ordinary cooking breaks but part of the food cells. This method breaks them all.

Puffed Rice is whole rice puffed in like way. Corn Puffs are pellets of hominy puffed.

Where ease of digestion must be considered, these are the ideal grain foods. They are also the most delightful grain foods that anyone ever tasted.

MEDICAL COLLEGE ADMITS WOMEN

For the first time in its history, women have been enrolled in the Medical College of New York University. They will have equal privileges with the men, will work in the same laboratories and clinics, and will receive their degrees after completion of the same curriculum. The location of the college gives students an opportunity to deal with health problems as it is in close proximity to Bellevue Hospital, the largest public hospital in the world. They are permitted to attend the hospital clinics and assist the attending physicians in dispensaries.

LEAGUE OF RED CROS SOCIETIES

The General Conference of the League of Red Cross Societies held in Geneva in March declared as its objective "the prevention and maelioration of those ever present tragedies of unnecessary sickness and death which occur in the homes of all people." Especially are its activities t obe directed toward restricting and preventing those diseases which are due to ignorance and lack of application of well established principles and practices which will contribute to health and welfare.

The program outlined by the medical section embraces the most important features of the care and welfare of mothers and children, the treatment and control of tuberculosis and other infectious and contagious diseases, the improvement of sanitation, the standardization of vital statistics, and the encouragement of the development of scientific stury along practical linesh affecting public health. In expressing the purpose of the League the report says it is endeavored to convey the spirit of this Conference. which strives for nothing less than for the improvement of the health and physical welfare of mankind. Immense labors are before us, but our path is now clearly defined. We have found here a true unity of purpose. We have been thinking and feeling in larger terms than those of national egotism. We have felt something of that universal kinship which could not find content in the well-benig of a particular people alone. We have seen also more clearly than ever before that the health of one people is related to the health of all; that as the germ recognizes no frontiers neither should the prevention and the cure.

MENTAL HYGIENE IN INDUSTRY

There is reported in the January issue of *Mental Hygiene* a report compiled by the late E. E. Southard, of a research being conducted by the Engineering Foundation of New York, preliminary to the movement for mental hygiene in industry. The program of mental hygiene in industry has grown out of the application of the modern conceptions of public health to industry. Reasons for unrest are traced to distinct psychic types. The practical handling of peculiar types, psychologic tests for personnel, the persons of consulted psychology, "grievance specialists,"—all make for industrial betterment.

The recent improvements in employment management and all activities dealing with industrial personnel show that industry is ready for the new movement, and employment managers everywhere are displaying the keenest interest in the new ideas.

Mental hygiene is nothing new in essence, but today's contribution is its organization for a systematic attack on industrial personnel problems.

(Continued on page 32)

SLEEP—The "Let-Down" That Builds Up

Neither food nor drink nor climatic change equals sleep as a health preserving agent. Spent energy can be adequately renewed only when complete relaxation is experienced.

Nature demands a "let-down" every so often in the mental and physical activities of every individual. If this "let-down" fails to come during the sleep period, it must come during the work period, when every minute costs money, when every second lost means delayed production, when dull, listless action means a sagging of efficiency. A brain befogged by fatigue cannot hope to produce a masterpiece of workmanship—nor its full quota of effort.

Sleep without relaxation does not restore efficiency. Complete rest does.

The Sealy Mattress provides "balanced" support and that relaxful quality of sleep so indispensable to nightly recuperation and daily vigor.

This comforting tuftless mattress, consisting of an inseparably air woven, single batt of long fibre cotton, "gives" readily at those points where the body rests heaviest. It rises soothingly to fill in and support the arches of the back and other parts of the body.

Physicians, hygienists and public health officials who have investigated the Sealy have found that it meets every requirement of hygienic design, sanitary construction and physiologically correct service.

Note the Variety of Uses Afforded by the

ThermoLite
LIGHT AND HEAT INFUSER

Most therapeutic lamps designed for office or clinical use have a single large reflector with a high powered lamp in the center. This does not permit much adjustment in the intensity or illuminating area in front of the reflector, whereas with the **ThermoLite** (Triplex Type) the light can be projected in a curved or straight line, concentrated or diffused, to any degree, and all without focusing the rays.

Delivers Radiant Light and Heat in PARALLEL Rays

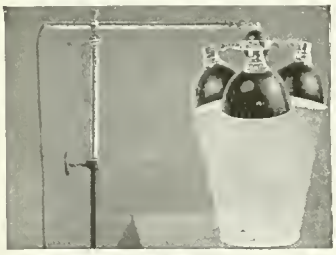
EXTREMELY EFFECTIVE IN THE TREATMENT OF

Neuralgia	Gastralgia	Rheumatism
Arthritis	Earache	Lumbago
Dermatitis	Laryngitis	Neuritis
Dismenorrhea	Mumps	Ulcers
Shingles	Bronchitis	Cystitis

and many other conditions.

Showing **Triplex** in lineal adjustment for spinal application.

The industrial clinic or hospital equipped with this scientifically designed therapeutic lamp can quickly relieve many conditions which otherwise would cause lay-offs of workmen and consequent reduction in industrial production.



Showing **Triplex** adjusted for concentrated application without focusing rays.

The delivery of radiant energy in parallel rays affords deep penetration, thus reducing inflammation and promoting healing in a most efficacious manner.

Showing use of **Simplex** (single lamp).

Send for prices and free book, "Photo-therapy."

ThermoLite is supplied in two forms—the **Triplex** for hospital clinics and office use, and **Simplex** (single lamp with or without stand) for home use.

NEW SYSTEM OF VOCATIONAL GUIDANCE

Dartmouth College proposes to give college boys a knowledge of their aptitude. Psychological aids will determine their types and their general grades of intelligence. A system of condensed records will follow their progress and note variations or affirmations of the traits identified. In this manner it will in many instances be possible to determine very easily the line of work that offers them the best chance of success.

As the work develops it will become possible to give the employer who is in search of recruits from the college complete and accurate information of candidates for positions. Such vocational guidance differs from vocational training, and the system obviously enables the application of physical and mental corrections and stimuli as they may be needed.

WAR METHODS IN CIVIL PRACTICE

In an address before the clinical section of the Royal Society of Medicine, reported in *The Lancet* of January 17, 1920, Sir Anthony Bowlby discusses the treatment of shock, choice of anesthetic, the handling of fractures and wound infections and antiseptics—all from the angle of the value of certain developments in war surgery applied to civil practice. Whatever we may have learned from the war, says Bowlby, there is inevitably much more to be learned in the near future. Without doubt the civilian surgeon will work even more with the bacteriologist than he did before the war. Transportation and first aid service for the wounded in civil life should be better provided for. Shock can be better treated and often can be prevented. Anesthetics can be rendered safer. No antiseptic can at once sterilize infected wounds. Delayed suture is an important advance in surgical technic, and suppurating wounds can be treated by improved methods.

American Medico-Psychological Association

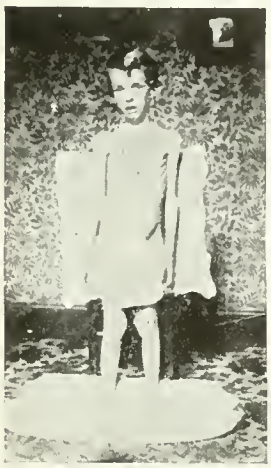
The annual meeting of the American Medico-Psychological Association was held in Cleveland, O., June 1 to 4, 1920. The program is well arranged to cover such special questions of administrative management and the technical side of the proper care of the psychopathic case, with due consideration of underlying causes, whether psychogenic or due to organic disease.

The awakened interest in the problem of the feeble-minded is shown by the discussions assigned to health workers in other fields, by the study of out-patient and dispensary clinics, by the important topics under the mental hygiene sessions. William A. White made a notable argument for the development of a program of mental hygiene of childhood. W. B. Cornell, Albany, N. Y., advocated the extension of individual mental hygiene to meet the urgent need of group mental hygiene to combat the present day mental ills of the group.

The papers presented in the Section of Clinical Psychiatry dealt with many phases of the question, notably the "Classification of Neuroses and Psychoses According to Their Affective Mechanisms," by Edward J. Kempf, M.D., Washington, D. C.; "Malingering and Simulated Disease," by Tom A. Williams, M.D., Washington, D. C.; the "Region of Psychopathology," by William A. White, M.D., Washington, D. C.; "Physiological Psychiatry," by Seymour DeWitt Ludlum, M.D., Philadelphia; and "New Speech Signs in General Paralysis," by Walter B. Swift, M.D., Boston, Mass.

(Continued on page 34)

ACUTE SUMMER DIARRHOEA



A virulent epidemic of diarrhoea swept Portsmouth. Several sufferers barely survived the first day. This boy of six was emaciated by persistent vomiting and copious, bloody evacuations.

When the virulence of the attack ceased, the doctor prescribed and continued VIROL for several months. This photograph was taken six months after the first.

THE role played by Virol in the treatment of infective diarrhoea has been elucidated by remarkable recent researches upon phagocytosis.

There can be no reasonable doubt but that the marvelous results produced by virolizing the diet of both breast- and bottle-fed children are due to the opsoninogenic properties of the preparation.

It has been conclusively proved that the addition of Virol under suitable conditions enormously stimulates the phagocytic powers of the white blood cells.

Virol is composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars: 50c, $1.00 and $2.00.

Liberal samples of VIROL and interesting literature will be mailed to physicians on request.

RATING OF BODILY MECHANICS

A physical examination of the first year Harvard men by Roger I. Lee, professor of hygiene, disclosed bad postures in 80 per cent and only 0.97 per cent were rated as having a good mechanical use of the body; 34.8 per cent used their bodies very badly.

"To be sure," says Dr. Lee, "their poor bodily mechanics is offset by youth and a physical condition otherwise good, but the result of this test certainly suggests that our preparatory schools might do much toward preventing poor habits of bodily use, and also that it is desirable for the college to undertake correction."

The good results of enlightment noted in the almost uniformly good condition of the teeth and the universal correction of ocular defects promise correction through physical education to bring to their best development the postural defects in these young men otherwise organically sound.

MORE FIELD AGENTS FOR HOSPITALS

Pursuant to a recommendation of the Hospital Development Commission, of New York, provision is made in the Appropriation Bill, recently introduced in the Legislature, for increasing the number of field agents in the State hospitals for the insane to the ratio of 1 to each 100 patients on parole, making 21 instead of 13 as at present.

One field agent for each of the State institutions for the feeble-minded is also provided.

The Development Commission's recommendation that the position of Director of Prevention and After Care be created to supervise the clinics and social workers was not acted upon favorably this year. It is hoped that this very necessary position will be created next year.

KANSAS A HEALTH RESORT

Kansas Health Figures for 1919 points out the fact that Kansas may go out and do some special advertising as a health resort. Dr. S. J. Crumbine, secretary of the state board of health, took the Kansas health figures for 1919 and made some interesting comparisons with the records of the government's registration area, covering those states where the death reports are regarded as absolutely accurate.

Improved sanitary conditions, anti-typhoid vaccination, and the vigorous preaching of common sense health rules to young mothers through the child hygiene bureau are given credit for the slumps in the typhoid and enteritis death rates.

The Kansas death rate from tuberculosis, heart disease, Bright's disease and even cancer is below that of the registration area by a considerable margin, and has been for several years. The rate is figured on deaths to every hundred thousand of population, and Kansas reported 112.4 for organic heart disease while the area reported 153.2. On tuberculosis Kansas showed a rate of 58.6 while the registration area reported 146.4.

For years Kansas was lagging behind the other states in the fight on typhoid fever. In 1917, the Kansas death rate was 19.2, while the registration area rate was 13.4. But last year the Kansas rate dropped to 7.7.

"The enteritis deaths, among infants less than two years old, always had been too high, but that condition prevailed over the entire country. Kansas was no exception. The number of deaths of infants from this cause has been almost cut in two in the last two years."

(Continued on page 36)

An Improved Arsenical

MON-ARSONE

For The Treatment of Syphilis

BY USING Mon-Arsone you entirely eliminate the disadvantages of arsphenamine without sacrificing any therapeutic value, for Mon-Arsone (disodiummonoethylarsone), a new and strictly ethical compound of arsenic, is non-toxic, non-corrosive and is supplied in a stable solution ready to inject.

So marked is Mon-Arsone's lack of toxicity that it has been administered in many cases of total arsphenamine intolerance without causing the slightest reaction while necrosis of the tissue never follows accidental extravasation from the vein.

From the important standpoint of therapeutic value, Mon-Arsone has been proved not only at least equal to arsphenamine but many cases are reported where clinical symptoms and the Wassermann have yielded even more promptly after treatment with Mon-Arsone than with arsphenamine.

A rapidly increasing number of physicians and hospitals have adopted Mon-Arsone exclusively. Can you afford to ignore its advantages?

Your orders will have our prompt attention.

The Harmer Laboratories Co. Philadelphia, Pa.

How About Infant Feeding This Summer?

You know what to expect in your baby cases when warm weather comes on. Bowel troubles and stomach upsets are sure to happen. You appreciate the need of the proper corrective element in the food formulas you specify. Have you tried

Mead's Dextri-Maltose

Prepared in three forms to meet specific feeding requirements and assist in **individual feeding?**

No. 1—With 2% Sodium Chloride. Of great value in feeding infants recovering from diarrhoea or with diarrhoeal predisposition.

No. 2—Unsalted—permitting the addition of salts as desired by the prescribing physician.

No. 3—Same as No. 2, plus Potassium Carbonate 2%. A corrective of constipation. Changes the calcium caseinate of cow's milk into a potassium caseinate. The curd is rendered soft, flocculent and soluble, hence properly digested and resulting in a soft stool that is easily expelled.

These three forms of Dextri-Maltose are offered for use in feeding formulas prescribed by the physician.

Shall we send you samples and literature pertinent to summer feeding conditions?

The Mead Johnson Policy

Mead's Dextri-Maltose is advertised only to the Medical Profession. No feeding directions accompany trade packages. Information regarding its use reaches the mother only by written instructions from her doctor on his own private prescription blank.

MEAD JOHNSON & CO., 304 St. Joseph Ave., Evansville, Ind.

STUDIES IN MALARIA. By Hugh Stott, M.B., B.S. (Lond.), Captain, I.M.S., licentiate of the Royal College of Physicians of London; member of the Royal College of Surgeons of England; Fellow of the Royal Society of Medicine; surgeon to His Excellency, the Governor of Madras. Cloth, 8vo, pp. 190, illustrated. Thacker, Spink & Co., Calcutta, 1916.

ESSENTIALS OF SURGERY. A Textbook of Surgery for Student and Graduate Nurses and for Those Interested in the Care of the Sick. By Archibald Leete McDonald M.D., the Johns Hopkins University; formerly in charge of the department of anatomy, University of North Dakota; lecturer on surgery, Nurses Training School, St. Luke's Hospital, Duluth, Minn. Cloth, 8vo, pp. 265, illustrated. J. B. Lippincott Company, Philadelphia, 1919.

INDUSTRIAL MEDICINE AND SURGERY. By Harry E. Mock, B.S., M.D., F.A.C.S., assistant professor of industrial medicine and surgery at Rush Medical College; attending surgeon St. Luke's Hospital; visiting surgeon to Washington Boulevard Hospital; chief surgeon to Sears, Roebuck & Co.; Fellow Institute of Medicine, Chicago; Lieutenant Colonel, Medical Corps, U. S. A. Cloth, 8vo, pp. 846, illustrated. W. B. Saunders Company, Philadelphia, 1919.

MENTALLY DEFICIENT CHILDREN, Their Treatment and Training. By G. E. Shuttleworth, B.A., M.D.; Fellow Kings College, London; consulting physician (formerly medical superintendent) Royal Albert Institution, Lancaster, for the Feeble-Minded of the Northern Counties; and W. A. Potts, M.A., M.D., medical officer of the Birmingham Committee for the Care of the Mentally Deficient. Cloth, 8vo, 4th Ed., pp. 284, illustracted. P. Blakiston's Sons & Co., Philadelphia, 1916.

ORTHOPEDIC AND RECONSTRUCTION SURGERY, Industrial and Civilian. By Fred H. Albee, A.B., M.D., Sc.D., F.A.C.S.; Lieutenant Colonel, M.C., U. S. A.; professor and director of Department of Orthopedic Surgery, New York Post-Graduate Medical School and University of Vermont; chairman Rehabilitation Commission of the State of New Jersey; member of Advisory Orthopedic Council to the Surgeon General. Cloth, 8vo, pp. 1.138, illustrated. W. B. Saunders Company, Philadelphia, 1919.

A TEXTBOOK OF CHEMISTRY FOR NURSES. By Fredus N. Peters, A.M., Ph.D., author of "Experimental Chemistry," "Laboratory Experiments," "Modern Chemistry," etc.; formerly professor of chemistry and director of laboratories, Kansas City College of Pharmacy; professor of organic chemistry, Hahneman Medical College; director of laboratories and professor of chemistry and metallurgy, Kansas City Dental College; head of science department, Kansas City Central High School. Cloth, 8vo, pp. 302, illustrated. C. V. Mosby Company, St. Louis, 1919.

PENSIONS AND THE PRINCIPLES OF THEIR EVALUATION. By Llewellyn J. Llewellyn, M.B. (London), late Temp. member appeals Tribunal Ministry of Pensions, senior physician and governor, Royal Mineral Water Hospital, Bath (Attached to Second Southern General Hospital), and A. Bassett Jones, M.B. (London), Temp. Captain, R.A.M.C., Military Orthopedic Hospital, Whitchurch, Cardiff, late Temp. Hon. Lieut., R.A.M.C., Welsh Hospital Netley, etc Cloth, 8vo, pp. 702. C. V. Mosby Company, St. Louis, 1919.

THE BIOLOGY OF THE BLOOD CELLS. With a Glossary of Hematological Terms. For the Use of Practitioners of Medicine. By O. C. Gruner, M.D., Lond., author of "Studies in Puncture-Fluids"; "A Code System for the Hospital Pathologist"; pathologist to the Royal Victoria Hospital and to the Maternity Hospital, Montreal; assistant professor of pathology, McGill University, Montreal; late clinical pathologist, General Infirmary at Leeds. Cloth, 8vo, pp. 392 illustrated. 21/. net. John Wright and Sons, Ltd., Bristol, 1913.

The Coffee Problem

We have solved the Coffee problem for Hospitals, Sanitariums and other institutions in our coffee plant. It is a large factor in our ability to supply a standardized product—to maintain a uniformity in the roasting and blending processes whereby we can meet continuously and confidently the requirements of our customers for coffees which they have found to their liking and in which they wish no variation as they purchase from time to time.

Many of our customers simply say: "Send us another drum of our coffee." Our records show what is wanted in each case, and our method enables us to duplicate exactly every time. This is our coffee standardization plan, by which we render a reliable and pleasing service.

Roasting and Cooling.

Grinding and Packing.

Bins for Various Blends.

ARISTON COFFEE-CEREAL BLENDS

And don't forget our Ariston Coffee-Cereal Blends, whereby we provide you a perfect coffee beverage (not in any sense a substitute), with real food value, reduced caffeine content, and at a substantial price saving. Only by trial can you know the merit of these blends, which are especially valuable for hospital use in serving patients who ought not to drink straight coffee.

Furnished in the following blends:

Ariston Coffee-Cereal Blend, No. 1, per lb.	$0.38
Ariston Coffee-Cereal Blend, No. 2, per lb.	.36
Ariston Coffee-Cereal Blend, No. 3, per lb.	.34
Ariston Coffee-Cereal Blend, No. 4, per lb.	.32
Ariston Coffee-Cereal Blend, No. 5, per lb.	.30

Let us ship you a trial order of 100 pounds. We guarantee the goods. If not satisfactory ship back at our expense.

THE DIAGNOSTICS AND TREATMENT OF TROPICAL DISEASES. By E. R. Stitt, A.B., Ph.G., M.D., LL.D.; Rear Admiral, Medical Corps, United States Navy; Commanding Officer and Head of Department of Tropical Medicine, United States Naval School; graduate, London School of Tropical Medicine; professor of tropical medicine, Georgetown University; professor of tropical medicine, George Washington University, etc. Cloth, 8vo, pp. 534, 3rd Ed., illustrated. P. Blakiston's Son & Co., Philadelphia, 1919.

PHYSICAL DIAGNOSIS. By Richard C. Cabot, M.D., professor of medicine in Harvard University; chief of the West Medical Service at the Massachusetts General Hospital. Cloth, 8vo, 7th Ed., pp. 527, illustrated. William Wood & Co., New York, 1919.

HEALTH THROUGH WILL POWER. By James J. Walsh, M.D., Ph.D., Sc.D., medical director of Fordham University School of Sociology; professor of Physiological Psychology at Cathedral College; lecturer of Psychology, Marywood College, etc. Coth, 8vo, pp. 228. Little Brown & Co., Boston, 1919.

HYGIENE AND SANITATION. By Seneca Egbert, A.M., M.D., professor of hygiene, University of Pennsylvania; formerly professor of hygiene and dean of the Medico-Chirurgical College; sometime Major, Medical Corps, United States Army. Cloth, 8vo, 7th Ed., Rev., pp. 554, illustrated. Lea & Febiger, Philadelphia, 1919.

ELEMENTARY BACTERIOLOGY AND PROTOZOÖLOGY. For the Use of Nurses. By Herbert Fox, M.D., director of the William Pepper Laboratory of Clinical Medicine in the University of Pennsylvania; pathologist to the Zoological Society of Philadelphia, etc.; Major, M.C., U.S.A. Cloth, 8vo, 3rd edition, pp. 222, illustrated. Lea & Febiger, New York, 1919.

A TEXT BOOK OF UROLOGY IN MEN, WOMEN, AND CHILDREN, Including Urinary and Sexual Infections, Urethroscopy, and Cystoscopy. By Victor Cox Pedersen, M.D., F.A.C.S., consulting physician to Selective Service, Headquarters New York; visiting urologist to St. Mark's Hospital, etc. Cloth, 8vo, pp. 991, illustrated. Lea & Febiger, Philadelphia, 1919.

DEMENTIA PRAECOX AND PARAPHRENIA. By Professor Emil Kraepelin of Munich. Translated by R. Mary Barclay, M.A., M.B., from the eighth German edition of the "Textbook of Psychiatry," vol iii, part II, section on the Endogenous Dementias. Edited by George M. Robertson, M.D., F.R.C.P. (Edin.), lecturer on mental diseases in the University of Edinburgh and Physician to the Royal Asylum, Morningside. Cloth, 8vo, pp. 331, illustrated. E. & S. Livingstone, Edinburgh, 1919.

MILITARY OPHTHALMIC SURGERY. By Allen Greenwood, M.D., Lieut. Colonel Medical Corps, U.S.A.; recently honorary Lieut. Colonel, Harvard Surgical Unit with the Royal Army Medical Corps, British Expeditionary Force. Including chapter on Trachoma, other contagious conjunctival diseases and gas conjunctivitis. By G. E. De Schweinitz, M.D., Lieut. Colonel, Medical Corps, U.S.A.; and a chapter on ocular malingering by Walter R. Parker, M.D., Colonel, Medical Corps, U.S.A. Cloth, 8vo, 2nd Ed., Rev., pp. 131, illustrated. Lea & Febiger Philadelphia, 1918.

SURGICAL APPLIED ANATOMY. By Sir Frederick Treves, Bart., G.C.V.O., C.B., LL.D., F.R.C., Eng., Sergeant Surgeon to H.M. the King; consulting surgeon to the London Hospital; late lecturer on anatomy at the London Hospital. Revised by Arthur Keith, M.D., LL.D., Aber., F.R.C.S., Eng., F.R.S., Hunterian Professor and Conservator of the Museum, Royal College of Surgeons of England; formerly lecturer on and senior demonstrator of anatomy at the London Hospital; examiner in the Universities of Aberdeen, Cambridge, etc.; and W. Colin Mackenzie, M.D., Melb., F.R.C.S., Edin., F.R.S.E., member of council of the Anatomical Society of Great Britain and Ireland; formerly lecturer on applied anatomy University of Melbourne. Cloth, 8vo, 7th Ed., pp. 702, illustrated. Lea & Febiger, Philadelphia.

Cafeterias and Lunch Rooms Are Common Sense Health Insurance

The physical and mental well-being of employes are important factors in the efficiency of every industry. Faulty nutrition is recognized as a detrimental condition for the satisfactory progress of school children, as well as preventing 100 per cent service from the employe. Properly conducted Cafeterias have proved their worth in bringing the individual up to par in both industries and schools.

Rest and Club Rooms, considered essential by many employers, add that element of good-will necessary for the complete co-operation of the employe.

As the largest Cafeteria and Lunch Room Equipment house, we are prepared to design a Cafeteria or Lunch Room to meet any special needs, or to advise on correct equipment and installation. Regardless of what is required, we can supply it—at a saving. We furnish everything for Rest Rooms or Industrial Clubs at a saving to you of time and money.

Successful installations all over the country testify to our ability in these lines. Let us assist you in the formulation of your plans.

Write for This Special Literature

Book G10—Lunch Room Book—Containing complete data on industrial Lunch Room installations.

Book G40—Rest Room Book—The whole story of the Rest Room.

Book G60—Employment Betterment—The story of what industrial welfare work means in actual results.

ALBERT PICK & COMPANY

208-224 WEST RANDOLPH STREET, CHICAGO, ILLINOIS

"I Know of No Better Device or Means of Restoring Respiration Than *The* LUNGMOTOR

"The instrument is simple in construction; it is fool proof and efficient."
Thus speaks

A Well-Known Industrial Physician*

Furthermore he says:

"On two different occasions I used it on two different patients for a shock during an operation. These patients had stopped breathing, marked cyanosis developed, and the pulse became very weak. Both were revived by the use of the Lungmotor. I feel confident that I saved the lives of five babies suffering from asphyxia neonatorum. I found it very useful in these cases."

The necessity of Lungmotor protection in your hospital—in your industrial plant, is evident from the large number of lives saved in other hospitals and plants with Lungmotors available.

The need may come tomorrow:—Be Ready:—Some day you are going to have Lungmotor protection. Perhaps after the next fatal accident, as 87% did last month. Why not that protection now and save that next life which might otherwise be lost?

"The Lungmotor and the Need of It" is the title of the New Booklet which is yours for the asking.

Lungmotor Company
711-C Boylston Street Boston, Mass.

ANTI-TUBERCULOSIS FEDERATION

A conference for the purpose of forming an anti-tuberculosis federation will be held in Paris, France, next October, according to a decision recently reached by representatives of the American, British, and French societies in Paris.

MAKE USE OF STATE LABORATORY

The free laboratory facilities offered by the Ohio State Department of Health are being used more extensively now than ever before says a writer in the *Ohio State Medical Journal*. Wassermann work in particular has been gaining, examinations passing the 2,000 mark in one month. Diphtheria, tuberculosis, and typhoid examinations during the months of July, August, September, and October far exceeded those of last year.

DISABILITY FROM INJURIES TO THE BACK

The periods of disability are unusually long in persons whose backs are injured in industrial occupations, says Dr. James Warren Sever, in the November issue of the *Journal of Orthopedic Surgery*, reporting on a study of 134 cases. An analysis of 37 cases in which the injury resulted from falling (Class I) shows an average minimum period of disability of eleven months. In 31 cases injured by blows from falling objects (Class II) the average minimum period of disability was 14.7 months. Injury from strain was noted in 42 cases with an aver-

THE HEALTH OF WOMEN

"There is a vital need for educating women to a proper valuation of their health," says Dr. Augusta Rucker, a New York physician and director of the division of health of the social education department of the Young Women's Christian Association. "In examining 414 successful business women recently, not one measured up to normal. These are intelligent women who are fairly representative of health ideals."

The purpose of health centers being established by the Young Women's Christian Association is to "keep women well—to prevent ill health rather than cure it." Lack of exercise and faulty eating play the most havoc with girls' health nowadays, says Dr. Rucker.

HEALTH PROBLEMS IN EDUCATION

The report of the Committee on Health Problems in Education to the National Education Association constitutes what is practically a Philippic against the needless sacrifice of life and waste of human power because of the lack of constructive development of the potential health and fitness of the children of our Country. Only in a small percentage of the entire school population are the physical defects studied and recognized, and only in a fraction of these are the detrimental defects effectively corrected. The importance of these matters is not appreciated, says the report, and the real danger to the children of the land lies in the ignorance, irresponsibility of, and neglect by adults entrusted with their care.

Drafted by compulsory education into the schools, the children should be assured of skillful and satisfactory health care. The Committee places its emphasis on health education. Its publications consist of three pamphlet reports and fifty-eight health charts, with other publications under way on "Health Improvement in Rural Schools," and on standards for "Health Norms and Health Defects of School Children."

DEFECTIVE THERMOMETERS

THE Department of Health of New York City has been performing an important service in making an investigation of the clinical thermometers offered for sale and, also, of those used throughout the city by institutions, doctors and nurses. The startling fact was disclosed that a large percentage of the thermometers in use were defective. The department, therefore, calls for regulation of the clinical thermometers manufactured for use and in use and urges a national law or regulation to prevent dumping into other states of thermometers found defective in New York City.

It is a trite statement that a defective thermometer is worse than no thermometer. False security or false fears may be encouraged by a defective thermometer.

We do not know to what extent the condition reported by the New York Department is due to the deterioration of thermometers or to dishonest manufacture and sale, but whatever the cause, the remedy is clear. Steps should be taken without delay by individuals, physicians, nurses, and by local, state, and National authorities to see that all clinical thermometers in use are correct. Already the state of Massachusetts has taken steps with respect to the manufacture and sale of clinical thermometers and in that state all clinical thermometers sold must meet the requirements of the Bureau of Standards. This law has been vigorously enforced and conditions are decidedly improved in that state. Manufacturers who have refused to correct their careless or criminal methods of manufacture have been denied licenses to sell clinical thermometers in the state.

That the condition is more widespread than has generally been believed is evidenced by the action taken by the authorities of France and Great Britain during the war, prohibiting the importation of clinical thermometers that had not first passed official laboratory tests. The Army and the Navy, and the American Red Cross took similar action in respects to the thermometers used in military service.

Fortunately the situation is one which can be quickly and completely reformed by honest manufacturers and by physicians, nurses, and hospitals acting individually and through public authorities. The conditions disclosed are so inimical to the health of the people as to require immediate and drastic action.

HOSPITALIZATION OF DRUG ADDICTS

THE American Medical Association at its meeting in New Orleans went on record in opposition to the ambulatory treatment of drug addicts. In doing so, the Association gave expression to the fact which is well known among physicians that hospitalization is necessary during the time of cure and immediate after cure. The well known craftiness of drug addicts makes it clear to any one that reliance cannot be placed upon them unless they are under the strictest control and supervision.

The conclusions of the Department of Health of New York, where the subject has been as acute as anywhere in the country, are well worth quoting in support of the action taken by the American Medical Association. In a recent report the Department said:

Treatment of the narcotic drug addict by private physicians prescribing and druggists dispensing, while the individual is going about, is wrong. The giving of a narcotic drug into the possession of an addict for self-administration should be forbidden. Until this is done

by law, all honorable physicians should aid in stopping this vicious practice.

The case of drug addiction that can be cured by ambulatory treatment is the rare exception, and so unusual as to make one think it impossible.

Physicians generally are of the opinion that ambulatory treatment is not good practice, and few doctors use this form of treating addicts; so it is believed that those so doing must be either ignorant of proper methods, or do so in bad faith.

With the authority of the American Medical Association and the experience of the New York City Department of Health, physicians will scarcely need additional proof of the necessity of hospitalization of drug addicts.

CHILD WELFARE AND HEALTH

WE are offering in this issue of MODERN MEDICINE an article by Dr. A. Levinson of Chicago on "Inhibition, a Prime Motive in the Training of Children," which constitutes the third of a series of contributions developing a comprehensive view of child welfare in its relation to sociological and psychological problems.

Dr. Levinson is the author of a book on Cerebrospinal Fluid and is associate editor of an annual book on Pediatrics published by the Yearbook Company. He is associate in pediatrics at the Northwestern University Medical School, associate pediatrician at the Michael Reese Hospital of Chicago, attending physician to the children's department of the Chicago-Winfield Tuberculosis Sanatorium, and attending physician to the Mount Sinai Hospital of Chicago.

The article for the August issue will discuss the sociologic aspects of the tuberculosis problem in children. Other chapters will present the problems of the school child, of the mentally defective child, and of the adolescent. The articles will discuss mainly the sociological phases of the problems, and we therefore believe they will prove of definite value to health workers everywhere.

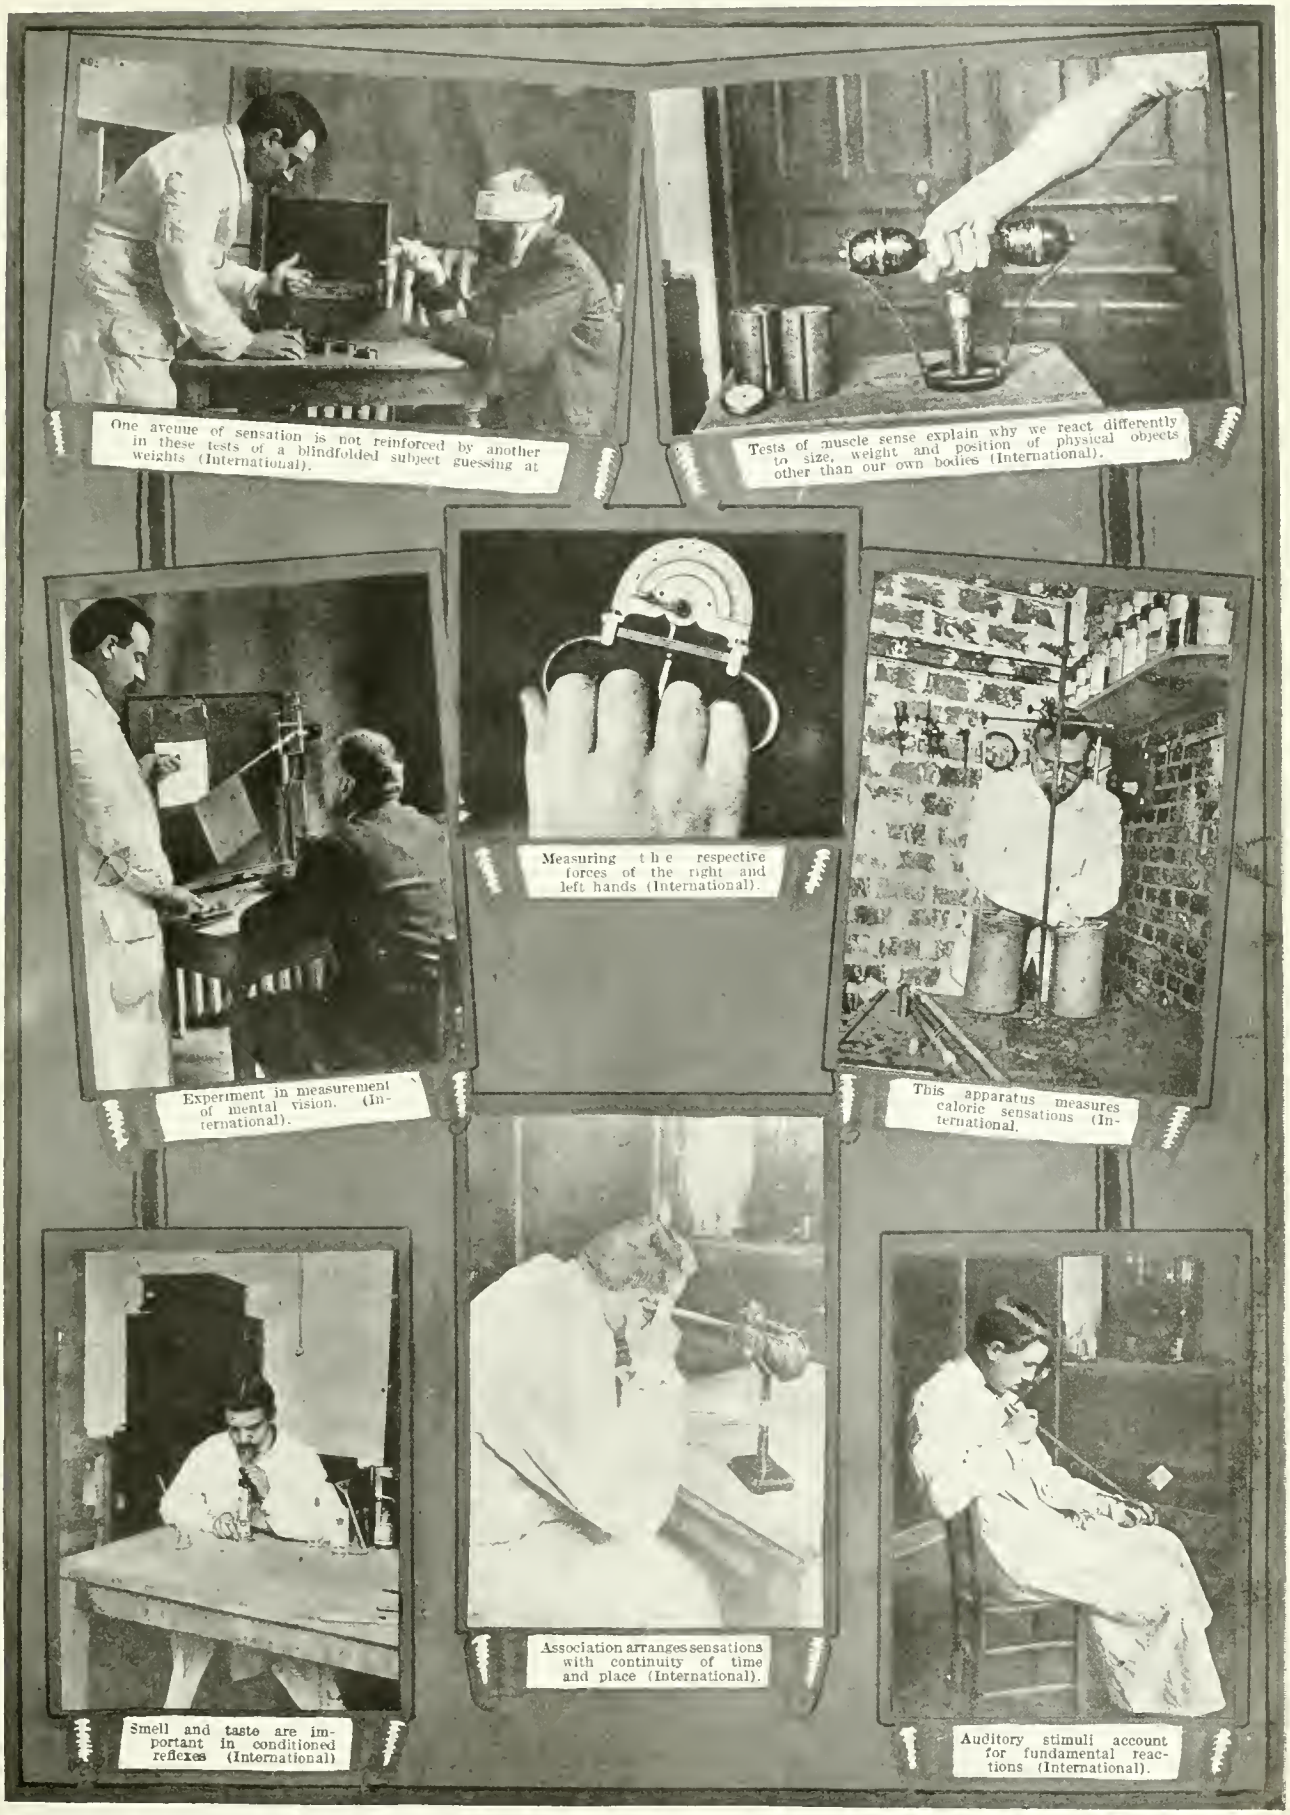
As the discussion in this series proceeds it becomes more and more apparent how numerous are the points involved in constructive work in this direction. The matter cannot be reduced to "pouring out stereotyped good advice on points of hygiene and diet." Racial factors are to be considered; the social background enters into the picture; hereditary traits and acquired habits are to be made serviceable, and aids to adjustment provided when necessary. That an adequate account of children's diseases is not confined merely to gross physical changes is particularly emphasized in this article on inhibitions. Habit distortions may arise in childhood that make later adaptations difficult if not impossible.

Pertinent to this discussion is the description given by Hector Charles Cameron, in his presidential address on maternity and child welfare work in England: "The medical officers of the welfare centers at present," according to Dr. Cameron, "are a heterogeneous body. Young and recently qualified officials, who know little of children in sickness and still less of children in health, whose opinion can carry little weight, either with the mothers or the health visitors; men skilled in general practice, who find the absence of pathological interest unstimulating; medical officers of health who, though very well versed in the study of faults in environment, have less knowledge of the common reactions of the child to these faults, and whose manifold duties permit them to maintain only nominal control over the health visitors, who are therefore left to pursue the work according to their own ideas:—none of these is likely to conduct the infants' center satisfactorily."

Gerald B. Webb, M.D., Colorado Springs, Colo., heads the National Tuberculosis Association.

Still less satisfactory is the perfunctory service of the young practitioner who attends the clinics while he is gaining experience in some other specialty which interests him more. There is no specialty more worthy of emphasis than the study of childhood. Undergraduate and postgraduate courses need to be offered so as to provide professional equipment. "We are not yet equal to our opportunities," continues Dr. Cameron. "To deal wisely and successfully with each mother and each child calls for professional gifts of the very highest order. To determine in each case where success is hanging in the balance; how far inherited tendencies or congenital weakness is responsible; how far dietetic errors; how far faults of management or handling; how far infection and of what parts—all this demands a wide experience." It is a subject difficult to learn, difficult to teach, difficult to write about; hence we offer these fruits of the wide experience of Dr. Levinson as a present help in a highly important field of endeavor.

S. P. M.



One avenue of sensation is not reinforced by another in these tests of a blindfolded subject guessing at weights (International).

Tests of muscle sense explain why we react differently to size, weight and position of physical objects other than our own bodies (International).

Measuring the respective forces of the right and left hands (International).

This apparatus measures caloric sensations (International.

Association arranges sensations with continuity of time and place (International).

Smell and taste are important in conditioned reflexes (International)

Auditory stimuli account for fundamental reactions (International).

MEASURE OF PERSONALITY

WHATEVER may be the realities of the external world, objects are interpreted to the human mind only in terms of the sensations registered on the sensori motor system which in turn become the stimuli to action. The attributes of objects are determined by the sensations they produce, and get their meanings from the manner in which we react to them. Personality becomes the sum total of such organized sense impressions, and behavior may be defined as individual reaction to environment. Psychologists were formerly reduced to introspection for the study of mind,—a method that led far afield; for the mental process to be observed changes when the attention is focused upon it, and a confusion resulted which caused the older psychologists to resort to mysticism or dualism to explain mental phenomena which have now come into the realm of the physical laboratory and, by means of sense instruments, can be accurately measured.

Sense impressions and their motor equivalents are registered by delicately adjusted apparatus; a study of the reflexes enables the detection of the nerve paths evolved in the process of learning; conditioned reflex methods show the relation of the emotions to the bodily secretions, and the service of physiologic functions of glands in emotional crises.

The work of Pavlow and Bechterew in Russian laboratories developed the appropriate stimuli for certain fundamental reflexes. Cannon, followed by Crile, has worked out very definitely the emergency functions of the endocrine glands. The organs of response have lately received the most systematic analysis and observation by Watson and his associates. Says Watson, "Could we bring thinking out for observation as readily as we can tennis playing or rowing, the need for 'explaining' it would disappear." Efforts have been made to bring such responses under experimental control, and thought as *implicit language habits*, issuing finally in overt action, has in Watson's laboratory been made to serve psychological requirements.

Vaughan has recently reviewed editorially the work of Lipkin on the specialized areas of the cortex, association areas, and coordinations, bringing out the present knowledge of the physiologic basis of memory. Consciousness arising at certain junctions and disjunctions, personality studies become the observations of a reacting mechanism and the materials of the psychological laboratory may be divested of theory and mysticism, thereby becoming definite and of immediate practical application. It is possible, therefore, to study the organism at work, to determine and adopt the best methods of acquiring serviceable habits, to devise working conditions that will largely eliminate fatigue, and to evaluate the "emotional and environmental changes that produce fluctuations in efficiency."

S. P. M.

INHIBITION, A PRIME MOTIVE IN CHILD TRAINING

By A. LEVINSON, Chicago

OF late, we have been hearing much about new ideas and new systems of education. Every inventor of a new system criticizes the old that he is attempting to supersede, and seeks to demonstrate wherein his plan is an improvement on the one in vogue at the present time. Most of the modern systems of education, beginning with Rousseau and ending with Montessori, have in common the one characteristic that they all insist on bringing out the individuality of the child, which they say should be permitted free play for its development. "Let the child develop his own ideas, and work them out according to his heart's desire," is their slogan. The teacher, say the most modern pedagogues, should be only an "observer" and not a disciplinarian. The same advice is given to the parents, who are warned against interference with the child's rights as an individual, and against repression of his natural instincts. A better, a more moral generation, is the result that the exponents of the "new" educational systems promise to those who obey their injunctions.

Need Protective Inhibitions

Does the end justify the means? Are not the children of our generation less moral, less kind, less capable than the children of generations ago? These and others are the questions necessarily asked by people who have made a comparative study of the old and new systems of education. It cannot be denied that former generations produced a better class of men who, morally at least, were greatly our superiors. It is a fact, too publicly aired to be contradicted, that divorces, holdups, and murders are greatly on the increase. Recent exposures have opened our eyes to the great numbers of our "pillars of society" who have turned out to be men and women devoid of all moral fiber.

What is the cause of this sociological phenomenon? To my mind only one explanation is to be offered and that is the lack of inhibition of the people of our generation, due to inefficient training of the inhibitory centers, a factor that used to play a great rôle in education years ago.

What is it that prevents a person from murdering or robbing or doing anything that his baser motives impel him to in moments of anger or madness? Many of us have such desires at times, in one form or another, but we check ourselves; we stop to deliberate; we "control" ourselves and our brutal impulses. It is lack of control that makes certain individuals act on the spur of the moment, and execute their actions immediately upon getting the impulse.

Whether or not we believe with Fleschig that there are association centers in the brain, one of which is the center of inhibition—self-control, attention, concentration, and volition,—we must admit that desires can be controlled by will, by restraint, and by training. We have but to look about us at some of the people we know to realize that it is very possible to keep within the "golden mean" in many things. When we admire them for what we term their self-control, we are at the same time paying tribute to the result of their training of their inhibitory centers. As for the value of inhibition, no one can doubt it. What would become of the world if there were universal lack of this means of control? It would swim in pools of blood about our feet. Nor do we need to limit our observation to outward actions to estimate the value of inhibition. Even the heart needs inhibition. Without inhibitory fibers the heart would run away with itself, the consequences of such an action being well known to every physician.

Of course there are exceptions to the rule of inhibition, as to any other rule; there are times, as for instance in the case of the rescue of a person from danger, when it is well that the inhibitory impulses are buried beneath the stronger impulse toward immediate action. The crises that demand these moments of heroism, however, are rare in the life of the ordinary man and woman, and such lack of inhibition may well be pardoned. In the world of ideas we meet with another exception—that of genius. A genius uses little inhibition when it comes to the expression of his ideas. As soon as the inspiration seizes him he hastens to express it to the world in a message in one form or another. "One of the impulses of genius," write Hogan, "is irresistible impulsion." One of the prophets of old voiced the same idea in the words: "There is a spirit in man, and who can overcome it." This lack of inhibition leads to a good end; and yet, whether or not we accept Lombroso's interpretation of genius in terms of insanity, some control of the inhibitory center must be insisted upon for the ordinary man even at the expense of losing a genius.

To develop men with control we must begin our work with the children. The brain at birth is especially weak in its inhibitory fibers. This explains in a measure why the infant urinates the minute the impulse is transmitted to its brain. It is, therefore, important for the mother to teach the child to ask for a vessel whenever necessary so that the child will not continue what becomes a bad habit if not restricted in time. With the development of the child comes a corresponding development of the inhibitory power, tending to self-control. This is in accord with the good old adage, "One good deed brings on another." It is the impressions made upon the brain that finally go to form a habit.

Years ago parents and teachers were aware of this fact and they made it their business to teach the children self-control together with the three "R's"; the mother would say to the child, "Sonny, don't go to the boiling pot, it is hot," and, to convince the child, she would blow the hot vapor so that he could see it. The teacher would follow up the teaching of inhibition by telling the child the right and wrong thing to do under the circumstances. And the child absorbed it all.

Now we go to the other extreme. The modern mother, true to the teachings of the modern educational texts, does not tell the child what to guard against. She leaves it to him to find out whether the pot is hot, or the revolver dangerous. Very often the child finds out all too soon by bitter experience.

Unless our parents and teachers arouse themselves to the realization of the value of inhibition as a factor in the education of the child, it is greatly to be feared that the future will produce many a rough example of self-developed individuals. At this very point it should be explained that we do not mean to say that teachers should tell their pupils all the evil they can think of and caution them against this and that. The mother who left her children with the injunction, "Whatever you do, don't put beans up your noses," soon discovered the mistake she had made in awakening a desire for something that would never have occurred to the children if left to themselves.

The teaching of inhibition is to begin at as early an age as possible. When the child begins to grab things from the table, when it speaks of mamma as "bad mamma,"—that is the time to enforce a little inhibition. As the child grows older, it is well and necessary to restrain it from over-eating, from eating too frequently, from snatching things that belong to others, from asking for pennies, and the like. By the time the child reaches the age of twelve or thirteen he will know that the first impulse is not always the best, will know that it is good to refrain from talking at times, and to think three times before speaking once. It is good for our boys and girls of adolescent age to know that not all passions, not all impulses are to have full sway. They will also know how to meet the many problems, how to fight out the internal struggles that developing years bring with them. The training of years will teach them how to face the problems that confront them, how to keep the reins in their hands, in short—how to control themselves. And the result of the conquest will be—better men and better women.

The Vltava (Moldau) River, Prague.

A PUBLIC HEALTH SURVEY OF PRAGUE, CZECHO-SLOVAKIA

By PHILIP S. PLATT, M.A., New Haven, Conn.

THE survey of the public health of Prague, Czecho-Slovakia, of which this article is a brief description, was made during portions of July, August, and September, 1919, while the author, then First Lieutenant, Sanitary Corps, U. S. A., was attached to the American Relief Administration, Prague, assisting in organizing the feeding of 600,000 especially under-nourished children, and in charge of the feeding of 50,000 children in and about Prague. It is a part of a social welfare survey of Prague, made under the direction of Miss Ruth Crawford of the Young Women's Christian Association, at the request of Dr. Alice Masaryk, president of the Czecho-Slovak Red Cross. It is appearing in Czech, with its five companion surveys, "The Social Care of the Individual, Women in Industry, Education, Recreation and the Church," at the expense and under the auspices of the Ministry of Social Welfare.

An Epoch Making Enterprise

Dr. Ladislav Procházka, the eminent health officer of Prague, in his preface to the survey writes of the new era in public health which is dawning for his country and of the part America is playing in this awakening:

This survey marks for us, the Czech hygienists, a certain epoch. Our contact with the outside world moved through German channels; our methods of public health research and analysis were German; and because our methods, after the German manner followed almost entirely the line of scientific research inadequate consideration was given to the needs of practical life, and practical hygiene suffered.

We had read and heard of American hygiene and the methods employed, but through personal contact we realized the full depth of difference. In the first place, there is the difference in people; the getting down to facts, the poise, the energy, the distaste for needless writing and talking, the firm resolve to see action and give real help, and a peculiar ability, almost stubborn, to penetrate to the very core of existing conditions in order to examine unhealthy roots where leaves are dying on trees. A difference between the attitude of our Republic and of the American state toward public health is also evident. In America the commonwealth and the citizens are absolutely convinced that public health constitutes an important factor in life and in public administration; this accounts for the splendid schools for hygiene, for social work, and for the training of nurses; this also explains the existence of their model institutions and hospitals, the donations of millions—which run into billions in our money—and the support given by individual men of wealth; out of this have grown the worthy and deeply grounded organizations, such as the Young Men's and Young Women's Christian Associations.

The opinion which was built upon the deep foundation of careful study, information and five months' work among us by an American expert is a gift to us and stands as an example of how to consider public health. Our fervent hope is that public health in this country may receive the great attention given it in America; that such men of energy, depth and warmth of feeling may be fully trained for expert work and be consecrated to public work as is the man who speaks through the pages of this survey.

America has showered our Republic with gifts. Quietly, without useless talking, she saved tens of thousands—perhaps hundreds of thousands—of children; she dried the rivers of tears; she removed from the heart the care as heavy as millstones with her huge gifts of clothing,

To the right is shown the National Opera House as it appears from the Vltava River. Below appears the old palace of the kings of Bohemia surrounding St. Vitus Cathedral. These pictures suggest little of the national housecleaning, both municipal and national, necessary at the close of the war. Twenty-seven girls were selected from the Czech-American summer school for social workers for intensive training according to American standards in medical social service, case work, recreation, and police court work. The activities they initiated and participated in form the subject of this paper. The man on the left is a typical Czech-American Legionaire. Hygiene being made attractive forms the message to the children in the upper left-hand picture.

underwear, and shoes. No complaint, no wish was expressed that was not answered willingly and quickly. She sent us people, whose friendship and cooperation became the source of happiness and pure enjoyment. She made and left to us the splendid organization of The Care of the Child—**Péce o Díte**" which today feeds with American food for 600,000 children in the Republic; and this book expresses that same spirit of kindly good will, that same desire to help which I consider so valuable a part of America's gift to us, I would say America's loan to us, which for the time being we can honor only with an honest, Czech, cordial "Zaplat Pámbu"—"God Repay You!"

Difficulties of Situation

Whether it be for public health or social welfare or business opportunity or inspiration, the deeply sincere leaders of Czecho-Slovakia, the sturdy New Republic of seventeen months, look instinctively toward America. America was one of the first countries to recognize Czecho-Slovakia. From America came their own hundred thousand Czecho-Slovak légionnaires who in France, Russia, and Siberia brought undying honor to their country. From America came the food that kept their children from disease and death. Their faith in us even today, after grievous disappointments, is stronger and more sincere than toward any other nation.

Czecho-Slovakia, like the other young nations reborn in the war, faces great problems. At the end of four years of unapproved, inforced participation in the war, but two weeks before the signing of the armistice, it overthrew its hateful allegiance to the Austrian Government and reëstablished its independence, lost on the field of battle three hundred years before. Drained by war levies, it emerged trailing the heritage of Austrian laws, traditions, and bureaucracy. The work of reconstruction involved not only the laying of new foundations, but municipal and national housecleaning from top to bottom. Yet behind closed borders, under straightened financial conditions, in the face of most difficult political conditions and with Bela Kun's army overrunning its Slovakian lands, the Republic and its

municipal governments have made real progress towards the splendid programs to which they are committed. Still, it would be manifestly unfair to compare, without making due allowances, the conditions in Prague today with those existing there before the war or with those existing today in other countries not seriously affected by the war.

Like all the war stricken cities of Europe, Prague has suffered the most profound disturbance to its normal values of life and death. One-half as many children were born in Prague in 1918—7.10 per 1,000—as in 1914—14.11 per 1,000—and the birth rate in 1914 was one of the lowest in Europe. On the other hand, the number of resident deaths increased, though by no means to so great a degree. In 1913 the death rate was 13.51; in 1918, 17.42, approximately what it had been ten years previously. The most important cause of this increase was unquestionably tuberculosis, though increased numbers of deaths from pneumonia, old age, and influenza play a large part. The other infectious diseases remained at their usual creditable rates. The population of Prague and its five main suburbs has fluctuated during the war from 493,913 in 1914, to 448,703 in 1915, and to 485,966 in 1918.

Fluctuations in Resident Population of Prague

The Number of Births and the Number of Deaths; the Crude Birth Rate and the Crude Death Rate; the increase of Births Over Deaths; and the Population; for the 10-year Period 1909-1918 for Prague and Its Five Main Suburbs.

Year	Number of Births	Number of Deaths	Increase of Births over Deaths	Births per 1000 Population	Deaths per 1000 Population	Population
1909	9,103	7,686	+1417	18.73	15.82	485,932
1910	8,498	7,526	+ 972	18.25	16.16	465,756
1911	8,303	7,792	+ 511	17.53	16.45	473,579
1912	8,040	7,664	+ 376	16.70	15.92	481,299
1913	7,726	6,705	+1021	15.80	13.71	488,958
1914	6,971	6,673	+ 298	14.11	13.51	493,913
1915	5,150	6,777	—1627	11.47	15.10	448,703
1916	3,917	6,699	—2782	8.63	14.76	453,777
1917	3,563	7,710	—4147	7.80	16.88	456,721
1918	3,453	8,465	—5012	7.10	17.42	485,966
Total	64,724	73,697	—8973			

Tuberculosis is by far the most serious single cause of sickness and death in Prague. Almost one-fourth, 22.9 per cent, of the deaths occurring yearly are due to this single cause. It causes nearly as many deaths as all the other preventable causes of death combined. It has killed sixty-eight times as many as has typhoid fever. The average death rate from tuberculosis of residents in Prague, 356 per 100,000 population, is one of the highest in all Europe. Always high, it was fearfully aggravated by the war with its attendant misery and malnutrition. The marked decrease in the rate from 372 in 1909 to 302 in 1914 was more than lost during the war. In 1915 the rate was 354; in 1916, 387; in 1917, 408; dropping to 386 in 1918. The effects of the past five years will not show themselves fully for years to come.

The Masaryk League

To combat this great menace the health forces of the city are as yet but imperfectly organized, but progress is being made. A new national tuberculosis society has been recently formed—the Masaryk League—with a broad program and more than a million crown fund, with which the two older tuberculosis societies will soon be affiliated. Its opportunity lies straight before it. A law to make the reporting of tuberculosis compulsory is before the Assembly. The country possesses three large and excellently operated sanatoriums, while the city department of health has planned the establishment of four large farm colonies to care for 3,000 patients. Vacation colonies for scrofulous and anemic children are emphasized. The dispensaries, however, need to be greatly improved before they can be considered effective agents in combating tuberculosis. Of educational measures there are none worthy of the name.

Prague's infant mortality, on the other hand, can be compared not so unfavorably with that of other European cities. The average for the five years before the war was 166.5 per thousand births, and 140.2 for the five years during the war. The highest rate was in 1911, when 181.6 was reached; the lowest rate was in 1916, with a rate of 130.5. The following year showed an increase to 146.8; 1918 registered 143.3. The reduction in the number of children born was undoubtedly of some importance in reducing the mortality, but much credit must be given to the Society for the Protection of Mothers and Nurslings which through a baby clinic, an obstetrical clinic, a maternity home, and the distribution of milk to infants and nursing mothers, provided invaluable care for delicate infant life. But much remains to be done, and no effort can be too great in a great country where each infant life must fill the place of two other unborn lives.

The American Relief Administration's Czecho-Slovak Child Relief Bureau which was organizing the emergency feeding of 600,000 medically examined under-nourished children under fourteen years of age, exerted its influence for the establishment of a health center and milk station. In spite of many difficulties this was accomplished, the Czech Ministry of Food granting 70,000 crowns, the American Red Cross supplying the equipment, and the Society for the Protection of Mothers and Nurslings carrying on the work with the assistance of trained personnel from the Young Women's Christian Association and the American Relief Administration. The

Infant Welfare station started with a well babies' clinic, a sick babies' clinic, a gynecological clinic, and the distribution of modified milk pasteurized in the feeding bottles. Trained social service work was instituted and plans were made for effective educational work.

A Czech baby who wants more of the delicious cocoa furnished by the American Relief Administration. The "little mother" will probably have a short ration.

Prague can point with pride to her typhoid history. She has lived down her stigma as a typhoid city and has won a place among the roll of honor cities. The average yearly death rate per 100,000 population during the past five years, since the introduction of her new water supply, has been 2.7. During the five year period, 1891 to 1895, the average rate was 32.6.

The accompanying table gives the deaths and death rate from typhoid fever during the past thirty-eight years.

TYPHOID FEVER

Deaths and Death Rates per 100,000 resident Population, for the years 1881-1918, for Prague and its Five Main Suburbs.

Year	No. of deaths	Rate per 100,000	Year	No. of deaths	Rate per 100,000
1881	113	45.9	1900	57	15.4

1899	66	18.2	1918	13	2.7

**Inclusion of Yrsovice as one of the five main suburbs of Prague.
*Inclusion of Liben as the 8th district of Smaller Prague.

The interpretation of these data is particularly interesting for four periods are discernible, each period distinctive for the type of sanitation engaged in. The years previous to 1894, when the rate averaged around 30, might be called the period of negligible sanitary activity.

A serious epidemic in 1894 attributed to ineffectually filtered water drawn from the polluted river Vltava (Moldau) almost doubled the mortality. The community was aroused and to some extent educated regarding the typhoid problem. Certain steps were taken to improve the situation. A municipal laboratory for the examination of water and foods was established. Ordinances regarding the cleaning of privies and of sewers and the sprinkling of streets were passed. Special action was taken in regard to the building of privies, as many privies leaked and overflowed, contaminating well water and flooding cellars. During this second period temporary results seem to have been obtained, for the rate dropped gradually to 15.4 in 1900, but only to rise again within three years to 28.8.

The third period was marked by energetic sanitation of bad quarters of the town and by the great extension of a modern sewerage system at a cost of more than 20,000,000 crowns. An old, highly congested, insanitary quarter was completely demolished and modern buildings with water supply and sewerage system, broad streets, and squares, were erected. A great number of wells and privies were destroyed. The effect on the typhoid mortality of the district in question was striking, no deaths occurring in the four years that followed, 1906 to 1909. Furthermore, a modern sewage purification station, begun in 1902 and put into operation in 1906, greatly improved upon the insanitary practice of emptying raw sewage in the river. Results of these activities seem to be clearly shown in the rate of 1905, 8.7, and 1906, 5.5; while the average rate for the nine years intervening before the introduction of the new water supply was 8.5—a remarkable decrease from the 28.8 of 1903. It is attributable, so far as can be judged, very largely to general sanitation and improved methods of disposing of excreta.

The fourth period, beginning in late 1913, was marked by the introduction into the dwellings of the remarkably pure abundant water supply from the shallow and artesian wells sunk twenty-five kilometers distant from Prague and pumped directly into the city. For this splendid supply another 20,000,000 crowns were expended. The following year the rate fell to 1.6 and the average during the past five years has been only 2.7.

Communicable Diseases of Children

Only the briefest mention can be made of the other public health conditions of interest. The common communicable diseases of children are

Czech kindergartens are immaculate even at the feeding hour.

on the whole creditably low, the combined death rates per 100,000 from measles, diphtheria, scarlet fever, and whooping-cough having been as low as 24.5 1916). There can be a great improvement, however, in the administrative measures used to control these diseases. Measles and whooping-cough, which were reportable previous to 1913, were placed among the non-reportable diseases by order of the Imperial Austrian Bureau of Statistics.

These under-nourished children are two or three years under size.

The prevalence of venereal diseases was studied by means of a questionnaire which has recently been addressed by Dr. Janko to 367 physicians and answered by 151. In brief, it was found that there were under treatment in one week 759 cases, of which 235 were reported as new fresh cases.

Prague in 1904 was well in the van of those enlightened cities which recognized the necessity of caring for the physical welfare of their school children, but the early system has long since grown antiquated. At the present time it is being remodeled from a thoroughly modern point of view to meet the new needs and to adopt school nurses, more frequent examinations and better physical education.

Mention has been made of the excellent water and sewerage systems of the city. The milk supply, however, is lamentably bad,—bad as to quantity, bad as to quality, and bad as to method of distribution. Probably no one food commodity has suffered so seriously as a result of the war. Prague, and indeed the whole country, has been facing a milk famine for the past three years. A great milk producing country has seen its production diminished by about 95 per cent. The systematic and discriminating requisition and slaughter of milch cows by the Austrian Government was carried out to the maximum degree. The milk producing cattle of rather inferior quality that were left were subject to marked underfeeding because of lack of fodder. The milk yield per cow fell from an average of nine liters per day to four liters. The daily milk consumption of Prague fell from 300,000 liters per day in 1914, to 19,000 in the summer of 1918. The price of milk rose enormously, from six cents to thirty, forty, and fifty cents per liter. What milk was to be had was watered, and high in bacteria. Fortunately the practice of boiling milk as soon as received is a deep rooted custom of Bohemian housewives. To this habit we must attribute the fact that tuberculous infections among children are not even greater than the already large amount, for it is admitted that a large percentage, estimated at from 30 to 70 per cent, of the remaining milch cows are tuberculous.

The Child Relief Bureau of the American Relief Administration strennously urged the recommencement of the pasteurizing of the milk supply which had to be

One of the thousands of feeding stations established by the American Relief Administration for feeding undernourished children. A large out of door restaurant was placed at the disposal of the local committee at Prague.

abandoned during the latter part of the war, and after much effort this was begun on a part of the supplies handled by the five large dairies. The real difficulties of pasteurizing in the bottle under the present conditions, as detailed by the dairymen, were formidable and unsurmountable.

The restocking of the country with healthy cows is only one of those imperative needs of the war stricken countries that it will take long years to meet.

The Health Department of the city is on the point of undergoing a complete reorganization to accord with the creation of a Greater Prague with forty-two communes and close to a million inhabitants. The Department, with jurisdiction over only Smaller Prague with 218,000 population, was created by law in 1880 and presents an extraordinarily complicated character. Some suggestion of this may be grasped from the fact that two separate bodies administrate public health, one a purely legal body, composed of lawyers, which possesses full executive authority; the other a medical or sanitary body which actually carries on the public health work of the city, but without any independent executive responsibility. The health officer is the director of the medical body, known as the Bureau of Hygiene, but has not representation on the legal body, which is known as the Tenth Department of the City and which alone has power to present reports and recommendations to the municipal council.

This group of selected workers accomplished notable results under American direction.

The budget of the combined branches for the year 1918 was estimated at 1,018,594 crowns, ranking seventh in importance among the twenty-four divisions of the city budget. This represents 3.7 per cent of the total budget of the city and represents a *per capita* expenditure of 4.7 crowns. As the receipts were estimated at 309,824 crowns, the net expenditures would represent 3.30 crowns *per capita*, an expenditure which at the pre-war value of exchange of 5 crowns to the dollar compares very favorably with the health expenditures of cities of similar size whose health service ranks high.

Only a few of the interesting features of this budget can be mentioned in this article. The largest single item is for general administration and the salaries of the seventy-five employees; it represents 47.3 per cent of the total net expenditures. The next largest expenditure is for the operation of the Contagious Disease Hospital, a really model institution, which expends 21.6 per cent. A surprising item, third in importance, is the operation of eight public baths, which costs 12.5 per cent, while the laboratory's net expenditures are 2.8 per cent. Public health education and public health nurses cost nothing, because there are no such activities. One observes that the relative values of public health activities are insufficiently appreciated.

The system of district physicians, sixteen in number, who are not only public physicians to the poor but who are also local health officers of their sanitary districts, is interesting to note. There are also fourteen school physicians and three school dentists. School nurses are to be inaugurated this year.

The Health Department is unquestionably providing a valuable health service to the city, especially in controlling communicable diseases and in maintaining general sanitary conditions. It fails especially in the weakness of its attack on tuberculosis, venereal diseases and infant mortality, on the inadequacy of its milk and farm inspection, and in the lack of educational work, all of which could be effectively undertaken on its present budget if the time and money now devoted to activities of slight or no public health importance were applied to the really important problems indicated.

Public Health Workers

Unquestionably the most serious deficiency in the public health situation in Prague today is the lack of specially trained public health workers, whether trained nurses, public health nurses, health visitors, social workers, midwives, socially-minded physicians, public health administrators, or sanitarians. These fine edged tools of effective public health workmanship are woefully lacking. The standard of nursing does not demand and receive recognition and respect. Prague has long been accustomed to consider the nurse as a person inferior mentally and socially. Much intelligent thought and action are being directed

upon this problem, and the effect of the establishment of high standards and of the added prestige that public health nursing will bring, will in time turn the old prejudices into respect for so noble a profession. Trained social workers are coming to be recognized and the demand far exceeds the supply. The recent Masaryk School for Social Workers, brought up somewhere near the American standard by the brilliant demonstration of the Czech-American Summer School for Social Workers organized and conducted by Miss Mary E. Hurlbutt, of the Young Women's Christian Association, during the past summer, is besieged by applicants. School, infant welfare and tuberculosis nurses, and social workers, when trained, will find work awaiting them.

Public Health administrators are urgently needed in the new Ministry of Public Health, in the local health departments, and in the national health societies. A splendid step has been taken in this direction by the Rockefeller Foundation, which has offered five scholarships for the study of public health in America. Four chosen men are studying to day in the M. I. T.—Harvard, and Johns Hopkins' Schools of Public Health.

The Promise of the Future

This ancient, beautiful Slavic city has given ample evidence in the past of its ability to protect the health of its citizens. The inspiring words of its trusted Health Officer give more than promise that the steps which remain to be taken in order to place the public health of Prague in the foremost rank will be taken to the limit that the serious difficulties of the immediate future allow.

By nature Prague is richly endowed. Her beauty no one can forget. Her majestic river, dotted with islands, flanked by numerous parks, protected by castle and cathedral crowned hills, is the playground of the entire city. She enjoys a healthful climate and is spared the excessive summer heat of many European cities. She possesses the most important of all health necessities—an excellent water supply—and her modern sewerage system with purification station is constantly extending. Her typhoid fever is almost a thing of the past. Her experience with the common communicable diseases of childhood has, on the whole, been fortunate. In her public schools a system of medical examination of children has been in effect since 1904. Prague possesses a forty year old health department with a creditable record of service. To meet new conditions it is being reorganized under the inspiring leadership of a broad visioned, capable health officer and patriot. Prague is, moreover, aided in her fight against disease by three tuberculosis societies, a venereal disease society, a number of excellent hospitals and sanatoriums, a famous medical school, and a newly created Ministry of Public Health.

Her problems are many and the difficulties great. But with her record of past accomplishments, her zeal for advance, and the stimulating contact with American public health methods and ideals, no one can doubt but that she will march splendidly forward. Public attention is being centered upon these matters so vital to her progress, indeed to her very preservation, and out of this consciousness of public responsibility for public health will evolve a new era of prosperity and general well being of her people.

INSTRUCTION REDUCES INFANT MORTALITY

It is not just a happy coincidence that infant mortality has decreased as the intelligence of the mother has increased. "It is on the intelligence of the mothers that the conservation of our bodies depends," said Dr. L. Emmet Holt, in the *New York Times* recently. Dr. Holt is professor of the diseases of children at Columbia University.

A steady decrease in the number of reported deaths among infants from 1885 to 1919 has resulted from the general education of the community, the growing intelligence of the mother, and the increasingly important part played by the visiting nurse in the home.

"A generation ago for every one thousand infants born there were 280 deaths a year. In 1919 the figures show only 82 deaths per one thousand births, a reduction to less than one-third of what it was. As recently as 1890 26 per cent of all deaths were among infants under 1 year. Today the Bureau reports that they comprise only 14 per cent.

"The result of a well organized and well administered campaign of education in connection with infants is illustrated by the decreasing infant mortality in New York State. When Dr. Biggs became State Health Commissioner he introduced throughout the state the same general plan that had been inaugurated in the city, and the result has been that the mortality in the state has steadily fallen although it is still a little above that of the city where the educational work has been going on a longer time.

"Those who question the ultimate value of the saving of infant life and look upon these measures as simply a means of saving the unfit are answered by the figures. There has been a greater reduction in the mortality rate of the children under five years of age than of infants, as is shown by the following table, based on a child population of 1,000 under five, prepared by the Bureau of Vital Statistics:

1899	61.1	deaths
1908	50	"
1913	37.6	"
1919	24.7	"

"The same agencies which so materially reduced infant mortality brought about also a corresponding reduction in the mortality of adults as well as of older children. Again quoting the figures of the bureau, 'In 1899, out of a total population of 3,356,722, the death rate was 19.5 per 1,000, while in 1919, with a total population of 6,006,794, the death rate was only 12.4 per thousand.'"

Roentgenology and Radiotherapy

THE MENINGOCOCCIDAL ACTIVITY OF BLOOD

IN this investigation there has been another effort made to devise a method for determining the bactericidal action of blood upon a coccus,—in this case a meningococcus. One of the main difficulties in testing out in an experimental manner or *in vitro*, the bactericidal power of anticoccal sera is that no method has yet been developed to make this determination. It is easy to kill typhoid bacilli in the test tube with antityphoid serum. Streptococci, staphylococci, gonococci, and meningococci, however, are resistent. The biological reason for their resistence is probably the reason why it has been impossible to produce an efficient antiserum for most of these cocci. It is different, however, with meningococci, for there has been produced a very efficient curative and, therefore, a bactericidal serum for meningococci.

The work of Matsunami[1] with the Lacy-Heist method for determining the bactericidal action of blood against meningococci is very significant. It is interesting to note that he found that whole blood showed a distinctly stronger bactericidal action than serum. Also, it was found that the meiningococcidal activity *in vitro* of immune rabbits' blood was stronger than that of immune serum or defibrinated blood or blood cells in serum or citrated blood. This action of whole blood is attributed to the phagocytic action of the leukocytes. This would explain the fact that immune rabbit serum had no stronger meningococcidal activity than normal rabbit serum. The degree of meningococcidal power in any of these tests was small and, undoubtedly, not in proportion to the activity of antimeningococcus serum when used therapeutically. Therefore, in spite of the importance of this work the method cannot be used to test out the degree of bactericidal action of therapeutic antimeningoccocus sera.

ISO-AGGLUTININS IN INFANTS AND CHILDREN

THIS investigation has not only purely scientific value, but also a practical importance in demonstrating that the blood of an infant and its mother may belong to different groups. Happ[1] shows that it is not safe to transfuse an infant with its mother's blood without previously determining the blood group of each, thereby learning whether the two bloods are compatible. It is just as necessary to make these tests before transfusing an infant as for an adult. This fact is not generally known.

1. Happ, W. M.: Jour. Exper. Med., 1920, xxxi, 313.

Mother's milk was found to contain iso-agglutinins belonging to the same group as mother's blood. Since some nursing infants were found to belong to a different group than the mother, it is evident that the iso-agglutinins in the mother's milk did not pass into the infant's blood or determine the infant's blood group.

Several conclusions arrived at are of much interest. Iso-agglutinability of infant's corpuscles develops sooner than iso-agglutinins develop in the serum. The blood group is usually present at one year of age, and always present after two years. When the grouping has become established in both serum and corpuscles, it does not change.

W. T.

THE COAGULATION TIME OF BLOOD

RODDA[1] has devised a simple method for determining coagulation time, and in 126 new-born found this to average seven minutes in the first twenty-four hours of life.

The heel of the infant is punctured with the usual type of lance to secure a free flow of blood. The second drop is collected in a clean watch glass, one and one-half inches across. In the watch glass is a single No. 6 lead shot. A second watch glass is inverted over the first. The time is counted from the falling of the discarded first drop. The end reaction is said to be sharp and consists of fixing of the shot in the clotted drop of blood so that the glass may be inverted without dislodgement of the shot. At times the clot may move on the glass, carrying the shot with it.

The coagulation time may vary from five to nine minutes. After the first twenty-four hours of life the coagulation time showed a tendency to prolongation up to the fifth day, and returned to the original by the tenth day. This method was controlled by that of Lee and White[2] with blood secured by puncture of the superior longitudinal sinus. The average time was the same for both methods, with less variation by the watch glass method. Bleeding time, by Duke's[3] method was found to average three and one-half minutes, and showed the same general type of curve as the clotting time. Rodda believes his studies have shown that prolongation of both bleeding and coagulation time in the new-born indicates an hemorrhagic tendency or disease and should be treated by the subcutaneous injection of normal blood, which will prevent the hemorrhages. This investigation seems to have been very carefully done, the method is simple and seems accurate.

AGGLUTININS AND HEMOLYSINS

BLOOD tests *in vitro* done on the blood of the patient and prospective donor are absolutely indispensable to prevent serious accidents in transfusion. It has been generally accepted that in a general way iso-aggultinus and isohemolysins exist usually in the same serum in about the same proportion. It has therefore been believed that, if a very small amount of agglutination has been found in the patient's serum against a prospective donor's cells, the count of hemolysins will also be small. In the recent work of Ottenberg and Krasnow[1] they have definitely shown that, whereas, in general weak hemolysins parallel weak agglutinins and a strong hemolysin parallels strong agglutination, this is not always the case. On the contrary, they found that a strong hemolysin often occurs with weak agglutinins. Therefore, they emphasize very strongly that donors should be rejected whose red cells are even slightly agglutinated by the patient's serum, for such a case provides the possibility of an extensive hemolysis occurring in the blood. SILVER SALVARSAN SODIUM

KOLLE,[1] in Germany, has recently introduced silver salvarsan sodium in the treatment of syphilis. Preliminary experimentation as to the therapeutic value of the drug in syphilis was made with rabbits. It is understood that Kolle placed generous quantities of the drug in the hands of German clinicians[4,5,6,7,8] so that now the leading German medical periodicals are reporting the observations of these clinicians.

It is stated that this new antisyphilitic agent is more harmless than old salvarsan because the effective dose, 0.2 to 0.3 gm., is below the danger point for arsenic. The arsenic content of silver salvarsan is reported as 22.5 per cent, with 14 per cent silver. This arsenic content is about two-thirds that of old salvarsan. Silver is reported as catalytic to the arsenobenzol molecule, and is also said to reinforce the specific action of arsenic on the Spirochaeta.

It is claimed that silver salvarsan acts rapidly, is well borne, and that it has been used without severe reactions. From 1 to 1.4 gm. is considered sufficient for a single course of treatment.

Delbanco[9] reports 550 injections of the drug without untoward reaction. Boas and Kissmeyer[10] reported the use of 400 tubes of silver salvarsan on 62 syphilitics and think it equal to old salvarsan. Korsbjerg[11] used it on 32 patients with favorable results.

EOSINOPHILIC LEUKEMIA

THIS is an extremely unusual case reported by Shapiro.* There is apparently only one other similar case in the literature. The white blood cell count varied from 15,700 to 236,000 and the polymorphonuclear eosinophiles from 48.5 to 86.5 per cent. The disease was apparently a primary blood disease as borne out by the clinical and autopsy findings. All of the known causes of eosinophilia were ruled out in this case.

We are not accustomed to think of leukemia with the predominating cell in the circulating blood a polymorphonuclear leukocyte. Nevertheless, this case seems to be one of leukemia and will have to be considered as such for the time being. Large clinics should scrutinize their cases carefully to see if perhaps other similar cases may not be found, so that this condition can be further investigated and the disease more accurately classified.

The January to May, 1919, Volume of the *Proceedings of the New York Pathological Society* contains many other interesting cases and reports well worth reading.

W. T.

SUBGROUPING OF A SPECIES OF BACTERIA

SINCE the subgrouping of Pneumococci by Cole and his co-workers, studies have been directed along these lines with other organisms. The subgroups of Pneumococci, as determined by Cole, seem quite definite although this is not accepted by all workers. The criticism that these subgroups of Pneumococci show distinctive reactions only with low dilutions of sera is the main criticism which can be directed against this work. In spite of this criticism the best authorities have accepted this work of Cole.

Meningococci have also been divided into subgroups, the work of several English observers being mainly responsible for this. This subgrouping of Meningococci also can be accepted. Based on this work, anti-meningitis sera have been prepared for the different subgroups and have been found more effective therapeutically than polyvalent serum in cases where the subgroup of the individual organism is determined.

Havens[1] has recently reported that diphtheria bacilli can be divided by immunological methods into subgroups. He has also presented evidence that the antitoxins of these groups are somewhat different from one another, but that they are not as differentiated as the agglutinins for the groups. Nevertheless, he states that his investigation indicates that the effectiveness of therapeutic diphtheria antitoxin could probably be enhanced by making sure that in its production members of the second or smaller group of diphtheria bacilli were included.

All of the studies above noted seem important and seem to be definite contributions to our knowledge. A recent article by Small and Dickson[2] on the grouping of Bacillus influenzae, however, causes us to note that great caution should be used in explaining these ideas of subgroups for a given organism until a great deal of very careful work is done. The investigation of Small and Dickson was done with only a small number of strains of the organisms and should be extended before their results are accepted. We should be careful that this idea of subgrouping of different species of bacteria is not carried too far on insufficient data.

Variation, which is so universally present in organic life, undoubtedly occurs also with bacteria. It would seem much more probable that in most instances different strains of an organism vary slightly one from the other instead of falling into definite subgroups.

BLOOD VOLUME DETERMINED BY TRANSFUSION

IN a previous review attention was called to a method devised by Winifred Ashby of the Mayo Clinic for determining the length of life of transfused blood cells. If Group IV blood is transfused into patients belonging to groups I, II, or III, then blood can be withdrawn in a blood counting pipette and diluted with serum from a blood group which will agglutinate the original cells of the patient. In this way the unagglutinated cells can be counted, and these will, of course, be the original cells transfused. By this method Ashby determined that transfused cells persist in the circulation of the recipient for at least thirty days. A number of additional important findings are given in this second communication of Ashby. Ashby has modified the technic of this procedure in light of experience and the improved technic is the one to be followed.

The part of this communication which impresses one as being of greatest importance is that which explains how this method can be utilized to determine the blood volume of the patients. It becomes possible to make the red blood count and measure the amount of blood transfused and then by determining the number of transfused (unagglutinable) corpuscles in a cubic millimeter of blood, derive the blood volume of the recipient. Ashby's report on the subject of blood volume determination by this method, now under preparation, is awaited with great interest.

There seems to be no doubt that in Ashby's hands the procedure of counting the number of transfused unagglutinable corpuscles can be done with accuracy. The method appears simple, and thus should be available generally. Instead of injecting a dye, as is done with the method of Rowntree,[2] or of Whipple[3] and his associates, one injects a perfectly bland blood from a group four individual. With the dye methods the plasma volume only is determined directly, and the whole volume is then determined by the hematocrit method, which is well known to be open to criticism. With the Ashby method the total blood volume is determined directly.

The reviewer made some calculations from the figures given in Ashby's two articles and found out that the calculated blood volume came to about one-eleventh to one-twelfth of the body weight. These figures coincide with those which seem most accurate as obtained by other methods. It is to be hoped that the method of Ashby will be tried out in many places, as it is believed that it will be a great help in obtaining information as to blood volume in various conditions.

WATER LOSS IN SUMMER DIARRHEA

AT this time of the year, when respiratory infections are on the wane and "summer diarrhea" is beginning to take its toll among the babies, it is perhaps not inopportune to emphasize the importance which has been ascribed to "water loss," or dehydration of the tissues, in certain of the newer conceptions of the nutritional disorders of infancy. It has, of course, long been known that man can go without food for a much longer period than he can go without water; many physicians customarily prescribe water in large amounts during the course of certain infections, and particularly in the diarrheal disorders of children. The exact effects produced by marked loss of water from the tissues, however, are not so well understood, and have formed the basis for considerable speculation.

Marriott[1] has recently produced experimental evidence bearing on the pathology of certain nutritional disorders of infancy, in which the disastrous effects of desiccation of the tissues are emphasized. In the severe attacks of vomiting and diarrhea, so common in the summer, often for a time the amount of water eliminated from the body is greater than that ingested and, according to Marriott, there is produced the train of symptoms commonly referred to as "alimentary intoxication," "cholera infantum," or, as this author prefers to call the condition, "anhydremia." The blood shows a relatively high concentration of protein in the serum, and a low water content. There follows a diminished blood volume which results in a diminished volume flow of the blood and, apparently, a consequent alteration in the functional capacity of various organs, notably the heart and kidney. As a result of the diminished renal function, an accumulation in the blood of waste products ordinarily eliminated in the urine occurs, and not infrequently symptoms of uremia and acidosis are produced. Usually all of these symptoms vanish if enough fluid can be supplied to the tissues to bring the blood volume and concentration back to normal. Fluid is supplied by every available route, one of the best methods being the injection of large amounts of normal saline or Ringer's solution into the peritoneal cavity, 400 to 500 cc. often being absorbed in this manner with surprising rapidity even in babies. That the latter procedure, under the strictest aseptic precautions, is practically devoid of danger, is vouched for by Blackfan and Maxey[2] who first advocated its use in infants, McLean and Lang[3], and others. The circulation and blood volume may frequently be greatly improved also by the intravenous injection of 4 per cent glucose solution (10 to 20 cc. per kilo of body weight, according to Marriott), which has the additional advantage of acting as a food and diuretic. The measures outlined above constitute a distinct therapeutic gain in the fight against a disease which annually causes the death of many hundreds, if not thousands, of infants.

REFRACTOMETRY*

THE medical man of today realizes that the tremendous progress in the perfection of diagnostic means is to the largest extent to be credited to the successful application of principles and methods which were previously considered of purely academic interest.

It was therefore thought of interest to give a short account of a series of methods used in the examination of blood sera, which methods in turn are based on the use of the refractometer. We have attempted to avoid technical discussions and details as much as possible and can therefore only give a very general survey of the subject.

When a ray of light passes from a less dense to a more dense medium it is bent or refracted towards the normal, so that the angle of refraction will be less than the angle of incidence. The ratio of the sines of the angles of incidence and refraction is constant and characteristic for the media. Representing by i and r the angles of incidence and refraction we have $\frac{\sin i}{\sin r} = n$, the refractive index. The instrument used for the measurement of the refractive index is called a refractometer. There are several types of such instruments on the market. They were mostly made in Europe, but lately an American firm is manufacturing refractometers. The types best suited for clinical work are the Abbé refractometer (Fig. 1), the Pulfrich refractometer (Fig. 2), and the Pulfrich-immersion refractometer (Fig. 3). The operation of these instruments, especially that of the Abbé and immersion type, is simple. The immersion type must be used with the accessory prism. The amount of substance needed is very small, varying with the type of instrument used from one to ten large drops. Once the instrument is set up and connected with a thermo-regulating device, a single reading can be made in a few seconds. The readings are either direct or can be easily converted by means of tables furnished with the refractometer. The refractive index of a mixture can be calculated from the known specific refractions of the single components and, knowing the refractive index of one, the other can be calculated. It is this general principle that allows us to determine constituents of the blood such as serum-albumins and serum-globulins. For practical purposes it is often sufficient to simply compare a series of determinations with an established normal.

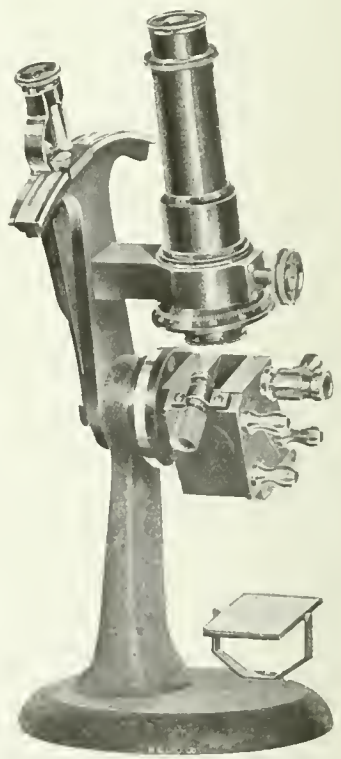

Fig. 1. The Abbé type of refractometer simplifies the use of this method of diagnosis in the clinical laboratory.

Strubell[1] reported on refractometric blood examinations in 1900. The methods used by Strubell have later been improved by Robertson[2] and by the researches of Reiss.[3]

*The author is indebted to C. Zeiss, Jena and to Bausch & Lomb, Rochester, New York, for the illustrations.

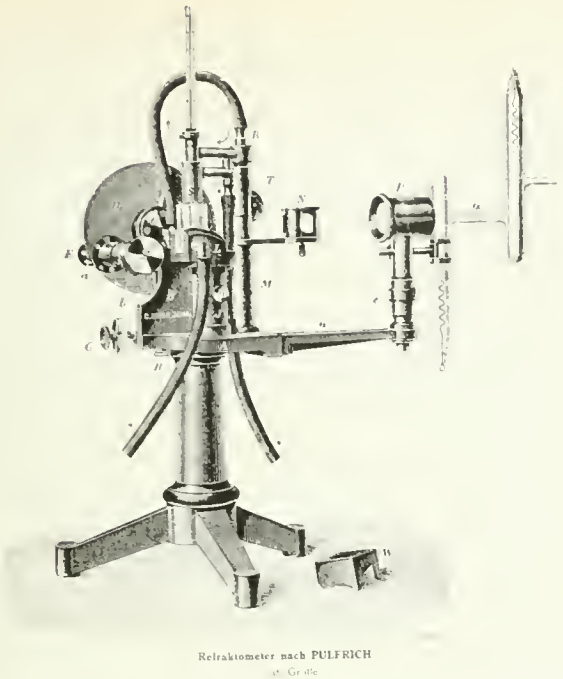

Fig. 2. The Refractometer of Pulfrich is the type of instrument used in much of the reported work in the determination of refractive indices.

In order to acquaint the reader with some of the methods, the principles of Robertson's technic are shortly discussed. Robertson modified the original method of Reiss for the estimation of total serum proteins in such a way as to permit the separate estimation of non-proteins, globulins, and albumins, besides the total proteins of the serum.

For the estimation of the non-protein constituents, the proteins of the serum are removed by heat coagulation in presence of acetic acid. The coagulum is separated by centrifugalization and the supernatent fluid is used for the refractometric determination. Taking into consideration the refractive index of the dilute acetic acid used in the procedure, the concentration of the non-protein substances can be calculated by means of a factor. To determine the amount of serum-albumin a small quantity (0.5 cc.) of serum is treated with an equal amount of saturated ammonium sulphate solution. In this procedure the serum-globulins are precipitated and the albumins can be determined refractometrically in the resulting clear fluid after proper dilution and taking in account the refractive index of the ammonium sulphate solution that had been added. After the refractive index of the serum has been determined, the calculation of the globulins is simple.

The work of Reiss on blood refractometry is very extensive. He compiled a table which allows a conversion of the refractometric readings into per cent of serum proteins. Reiss studied various factors influencing the refractive index of normal blood serum, such as food, liquid intake, muscular work, temperature, and blood letting. Among the numerous pathological conditions studied by Reiss we might mention: Bronchopneumonia, diabetes, nephritis, cardiac and circulatory disturbances, and acute infections. If we take, for instance, the case of chronic nephritis the simple refractometric determination will in many cases point to a liquid retention before actual edematous or similar conditions appear.

A considerable amount of work has also been done in this country in the last few years. Tranter and Rowe[4] studied a number of normal individuals, using the methods of Robertson. They found the variations in the protein percentage between 6.7 and 8.7 per cent, thereby agreeing closely with the finding of Reiss. The albumins were found to average about 6.2 per cent or 78 per cent of the total proteins; the globulins show an average of 1.74, or 22 per cent of the total proteins. Rowe[5] later found a higher globulin percentage in normal cases. In his examination of pathological sera he found a marked variation in the globulins of many cases. Syphilis showed a distinct increase in globulins, while the total proteins remained about normal. In pneumonia the globulin increase in relation to the protein is still greater although the protein total is decreased. An increase in globulins is noted in nearly all infections except those of a mild type; exceptions are also noted in acute tonsillitis and typhoid.

A study of the Wassermann reaction seems to point out that this reaction is not due to any increase in serum globulin. In his later work Rowe found an increase in the globulins of nephritic sera, which increase would again approach a normal level as death draws near. The non-proteins were found very high. Cardiac decompensation and arteriosclerosis showed a moderate increase in the globulins. Diabetes (without infection), hyperthyroidism, hemophilia, chronic bronchitis, pellagra, obesity, lead poisoning, gastro-intestinal disorders, and neurasthenia gave approximately normal results.

Hurwitz and Meyer[6] used the refractometric method to study the albumin-globulin ratio during immunization.

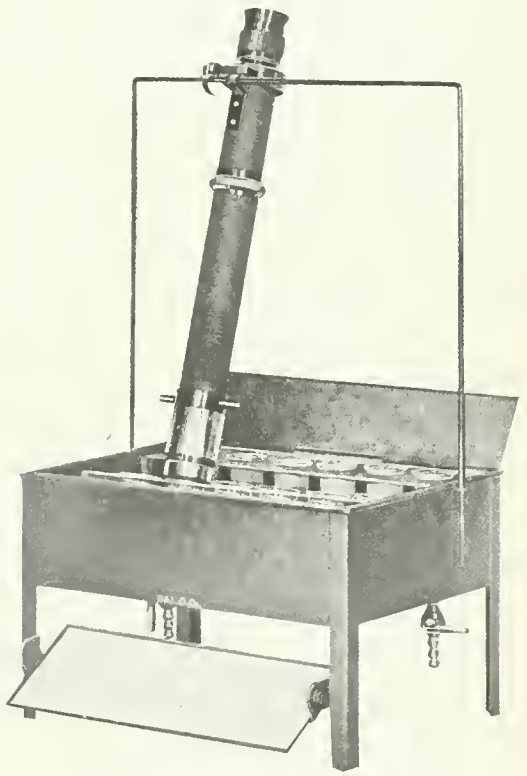

Fig. 3. The immersion type of Refractometer is used with the accessory prism. Once the instrument is set up and connected with a thermo-regulating device, a single reading can be made in a few seconds.

They find an increase in globulins long before any appreciable formation of immune bodies occurred.

The work of Rohrer[7] marks another step forward.

4. Tranter, C. L., and Rowe, J.: Jour. Am. Med. Assn., 1915, lxv, 1433.

5. Rowe, A. H.: Arch. Int. Med., 1916, xviii, 455; 1917, xix, 354.

6. Hurwitz, S. H., and Meyer, K. F.: Jour. Exper. Med., 1916, xxiv, 515.

Naegeli indicated the value of the relationship between the refractive index and the viscosity of the blood. Rohrer proved that the two above mentioned values are actually independent of the other serum constituents. Alder[6] using the findings of Rohrer[7] studied the albumin-globulin relation in the serum and found that the variation of this ratio in the individual is small. The findings of Rohrer and of Alder are the most promising, as we shall attempt to illustrate:

The serum protein content is increased from the normal in pulmonary tuberculosis, the increase is, however, slight, so that its diagnostic value is of no great importance *per se*. The albumin-globulin ratio is normally fairly constant. In tuberculosis, however, we find changes which show in extreme cases such an increase in globulin so as to reverse the ratio from a normal albumin-globulin 2:1 (roughly) to a ratio of 1:2. This is not specific for tuberculosis and has, therefore, to be used with caution; there is, however, the possibility of drawing conclusions as to the activity of the disease from the progressive increase in the globulins; in other words, there is the possibility of prognosis.

It is our opinion that the attempt should be made to include whole blood and not serum alone within the scope of future investigations. Whereas the work to this date will undoubtedly prove of the greatest value, the relation of corpuscles to the serum will serve as an additional help.

The above lines are, as indicated, merely an attempt to present a brief summary of the apparent importance of refractometric methods in modern medicine. The apparatus used is not extremely costly. The instrument is easily handled and does not require any changes in the laboratory, except for the Pulfrich (large) type, which has to be used with monochromatic light and therefore needs a dark room. The methods used in the handling of the serum previous to the refractometric reading are not more complicated than those used in chemical blood analysis. It is, therefore, to be hoped that these new procedures will find wider use and ultimately benefit mankind. J. C. B.

THE LA PORTE TREATMENT FOR CHRONIC OSTEOMYELITIS

THE claims made at the Chicago Medical Society for the La Porte treatment by the men who have been studying and experimenting with it, are so interesting that we feel they are worth publishing. The following statements are taken from the addresses and discussions of these men and not from our own observations or conclusions:*

The La Porte treatment, in brief, consists in the application over infected areas of aluminum potassium nitrate in an oatmeal poultice. The nitrate reaches the infected tissue through the skin by means of osmosis, breaks up into a nitrate, thus liberating nascent oxygen.

The aluminum potassium nitrate is formed by adding concentrated nitric acid to aluminum hydroxid; potassium hydroxid is added and the mixture is allowed to crystallize. This crystalline product is the salt used. The salt is then mixed with rolled oats which have been disinfected by being strained for two hours under a fifteen pound pressure. The proportion of salt to oatmeal is thirteen grains to the ounce. The oatmeal mixture is spread over a piece of gauze under which a piece of oiled silk or gutta-percha has been placed.

The poultice is then applied over the area of infection; the sound area adjacent is also covered. When this poultice is used over an area of chronic osteomyelitis with several sinuses it is found that within eight to twelve hours the serous discharge, which may have been present for years, is changed in character to a frankly purulent one; after twenty-four to forty-eight hours the skin becomes reddened, resembling an erysipelas; seventy-two hours later vesicles begin to form which soon change to pustules. These vesicles and pustules appear only over the diseased areas; the skin above and below, although covered with the poultice, remains clear.

At the same time that these pustules have been forming the discharge from the sinuses which at first may have been very scant has become very abundant. "The pus just rolls out," says Dr. Strauss. As the discharge becomes more copious, the tension in the tissues is relieved and pain subsides. The general condition of the patient also improves. The temperature becomes normal, the appetite increases, and many cases who have been bedridden are able to get up and get around.

The changes in the bone are slower. The free discharge drains the cavities. Sequestra becomes either entirely loosened and are cast off, or are "lifted out" surgically; or, in some instances, the sequestra actually heal in. The bone tends to resume a more normal aspect; the diameter of the shaft decreases; the cavities gradually diminish, as the case goes on to recovery; the pustules become umbilicated; the discharge lessens and finally ceases altogether; and the skin becomes free and pliable.

The application of the poultice brings about an autolysis and liquidation by means of which the dead tissue is cast off. It causes a marked hyperemia and hyperplasia of the blood vessels. At times in operative procedures—such as enlarging a sinus, draining a pus pocket, or removing a sequestrum,—undertaken during the course of treatment, there will be bleeding as if a hemangioma were being cut. Another result of the poultice is the increase in bacterial growth. The salt is not an antiseptic; on the contrary, it stimulates the growth of microörganisms. The discharges at first contain few organisms; later they are loaded with bacteria. This is not merely a skin contamination but a growth of the same organisms which were cultured before treatment. This bacterial activity stimulates the formation of antibodies and antitoxins.

The action of the salt is due to its passing through the skin as a dialysing membrane by osmosis. The nitrate changest to a nitrite, and nascent oxygen is liberated, the oxygen having a selective action for the diseased tissue.

The action is definitely selective. The reactions are obtained only if the poultice is applied over an infected area. If the poultice is used over healthy structures no vesicles or pustules will form. If the poultice extends over the healthy tissue adjacent to the diseased area, the vesicle and pustule formation will not appear except on the skin over the infection, although the whole skin area is bathed with pus. Application of the salt and poultice after healing will not cause any further changes.

The advocates of the La Porte treatment do not claim it to be a cure-all. They say it is indicated in chronic infections of bone and soft tissue; that it is not a substitute for surgery, but an adjunct to surgery; that by its use the extensive tunneling and lateral wall removal operations are replaced by simple opening of cavities, enlarging sinuses and lifting out sequestra. HELIOTHERAPY—NATURAL AND ARTIFICIAL

By E. H. SKINNER, M.D., Kansas City, Mo.

THE investigator of phototherapy encounters two very obvious facts: that this new treatment is, for anything still in its period of development, successful in a great majority of cases; and that the underlying principles of this method are as yet little understood. Various hypotheses have been advanced, but few of them with the required amount of scientific proof behind them, and frequently appearing contradictory of each other. The particular branch of phototherapy known as heliotherapy, sun treatment, natural or artificial, seems to have gained more favor in Europe than in this country, where attention has centered rather on the use of the x-ray or of radium. Rollier's sanatoriums in the Alps, and Finsen's Institute in Denmark, are perhaps the two best known of the several places on the continent which are devoted exclusively to this method of treatment. Rollier is the pioneer exponent of the treatment by the true sun rays, while the Finsen Institute régime is illustrative of the use of artificial heliotherapy as applied by the Finsen lamp. Reyn and Ernst[1] have demonstrated during the last five years that light treatment alone, without the cooperation of climatic influences, cured as effectually at the Finsen Institute at Copenhagen as Rollier's mountain climate sun baths.

Diseases to Which Applied

Heliotherapy has been applied to various types of disease, although its supporters warn against considering it as a cure-all. It has been most successfully applied in cases of surgical tuberculosis, ulcers and various kinds of sores, including war wounds, inflammatory conditions such as gout, arthritis, and in skin diseases such as lupus, acne, eczema, and psoriasis. Some instances of use of artificial heliotherapy in pneumonia and pulmonary tuberculosis are also recorded.

Heat or Ultraviolet Rays

In recent years the belief that the heat rays are the most beneficial factor has given way to a belief in the value of the ultraviolet rays, and hence we find the ordinary incandescent lamps less in use, while various lamps for producing ultraviolet rays in large quantities are being employed. The first of these ways, the carbon arc light, which is the type used by Finsen, the founder of this type of light therapy. The iron arc was introduced by Kjelsen as an improvement on the slow acting carbon arc, but although its proportion of ultraviolet rays was greater, there were impediments to its use, and in 1907 the quartz mercury-vapor lamp, known as Kronmayer's lamp, was introduced, which has since then become the foundation for the types in most general use. When faith in the power of the heat rays gave way to a belief in the efficiency of the ultraviolet rays, lamp makers were confronted with a difficulty in the fact that the ultraviolet rays are largely, if not entirely, shut off by ordinary glass. But quartz allows these rays to pass freely, and with the adaptation of the quartz tube to the mercury-vapor lamp came the possibility of having a successful source of light far richer in ultraviolet rays than is sunlight, and always accessible without regard to climatic conditions. For this reason some of the supporters of artificial heliotherapy consider it far superior to the use of the sun's ray, whether the carbon arc or the mercury-vapor lamp is the source to be considered.

Methods of Light Treatment

Reyn and Ernst,[1] in Denmark, use the carbon arc light, and in their experience with it since 1913 report a continuous series of cures. They claim the effect of these general light baths is something very different from the Finsen treatment of focused light. The aim in these baths is to have the body absorb as many of the chemical rays as possible. The exposures begin at short periods, from fifteen to thirty minutes, lengthening to two and one-half hours during the first week, which establishes the limit of duration for a single treatment. The general length of treatment for 156 patients was from four to eight months. Some of the cases were taking the localized Finsen treatment and began the general baths as supplementary to this. The general treatments were usually given every second day with a powerful current, although in tuberculosis cases there seemed great individual variation in the amount of current most effectual. The most striking cases were in osteitis and arthritis cases in many of which the joint healed without impairment of function.

From their experience the conclusion is drawn that the chemical rays are the effective element in light treatment, whether it be by Rollier's sunlight treatment or by artificial light.

Blegvad[2] reports twenty-four cases of tuberculous lesions of the larynx in which the universal light bath treatment as given at the Finsen Institute was used and in which six cases were marked successes, the lesion retrogressing completely. In thirteen other cases he reports marked improvement, while the remaining five cases, which seemed unsuccessful, he regards as still open to improvement by this method.

Collins[3] believes phototherapy to be still in its infancy, in spite of the great advances made in recent years under the leadership of Finsen, Rollier, and Reyn and Ernst. He speaks of the treatment of 133 tuberculous children in one of the seashore sanatoriums in Denmark, where the quartz mercury-vapor light is installed. These cases were those in which the general treatment had failed to show improvement and thus they were the more severe cases. In 102 of them general baths were given, in fifty-two merely local and in thirty-four regional baths, some being treated by associated baths. The average length of the course of light treatment was five months, the range being from six weeks to ten months. The thirteen cases of the 138 cases in which recurrence was observed he accounts for by the fact that the treatments were dropped too soon. Two children had tuberculous lesions other than those treated. In 108 cases the lesions were completely cured and in twenty greatly improved.

Advantages of Artificial Heliotherapy

As far as the expediency of this treatment is concerned, the greatest objection seems to be the length of time required. In the use of artificial light this may be short-

ened because of the fact that treatment can be as regularly and as frequently as desired. Further, the question of locality need not be considered and patients who are unable to devote their time exclusively to treatment or who are too weak to be transported to a distant sanatorium can be treated wherever an electric current gives opportunity to develop the required light.

Sun Ray Treatment

The supporters of natural heliotherapy differ in their opinions on some points. Rollier believes that the ultraviolet rays are exceedingly numerous in the sunlight but that the atmosphere, by its moisture and dust, prevents many of these rays from reaching the ordinary parts of the earth. Hence he considers it necessary to be located on very high ground and as far from cities as possible. Other exponents of heliotherapy have located sanatoriums on the seashore and seem to believe that the climatic benefit is a great adjunct to the treatment. On the other hand, others, among them Cololian and Frieburg,[4] hold that locality has little to do with its efficacy and think heliotherapy can be used as successfully in large cities as in any other place, provided, of course, that the air is reasonably free from smoke and the climate sufficiently rich in sunny days.

Sun Bath School

Armand-Delille[5] in 1917 organized a sun bath school like Rollier's at Leysin for the children of repatriated tuberculous women. The school is in a hilly region of Savoie. The children are clad only in trunks and play and study outdoors from eight in the morning to four-thirty in the afternoon. One month of this treatment was frequently enough to cause suspicious glands to disappear. Armand-Delille suggests heliotherapy as a regular part of child hygiene. Medical supervision is necessary as, especially in pulmonary tuberculosis, congestive reactions may be induced.

Points in Technic

In all types of phototherapy the surpassing importance of rigid technic is emphasized, whether the means employed be the artificial light or the sun's own rays; but in no method is this technic more specific or more rigidly insisted upon than in Rollier's method, which is based on a regular schedule for time and extent of exposure, beginning first with the feet, then the legs, the thighs, abdomen, and so on, with a definite number of minutes for the exposure of each part.

This method seems to be the one followed by Aimes[6] in his treatment of war wounds. Aimes says that sunlight is seldom used correctly for this treatment. In the relief of local pain and general soothing influence and the subsequent normal aspect and functioning of the muscles, and supplementary to operations, he considers that the value of heliotherapy is incontestable. With the majority of heliotherapists, he holds that the exposures should be direct, without the interposition of gauze, glass, petrolatum, or any fatty salve. If the essential element is the ultraviolet ray, the necessity of no intervening substance can be readily understood, since these rays may be interrupted so easily, even glass cutting them off more or less completely. Aimes also contends that total exposures are necessary in all forms of surgical tuberculosis, although in non-tuberculous affections extensive regional exposures may suffice. This point is not universally conceded, as some heliotherapists divide treatments into three classes, even using very limited exposures in some diseases. The rigid schedule adopted by Aimes runs: exposure of feet for five minutes first day at three sittings at least an hour apart. By the fifth day he is giving about three exposures; feet thirty minutes, legs twenty minutes, thighs fifteen minutes, abdomen ten minutes, and forearm five minutes. The forearm is exposed for five minutes on the seventh day, protecting the cardiac region. By the twelfth day he employs total exposures of an hour with only a half-hour for the trunk and neck. After the third month the whole body may be exposed for several hours. This means that the head is protected in such a way that the eyes are shaded. Since the sunlight is considered bactericidal, no antiseptic dressing are used in this treatment.

Cololian (1919) says the rigid Swiss method is too slow and he begins by exposure of the affected part the first day for five or six minutes; the second day there is a regional exposure of about twenty minutes; and in cases where the patient seems ready for it he gives a total exposure on the third day, with head and genitals protected, of about twenty minutes. He adds that the cure should be prolonged for two weeks or a month after the healing of the wound. He says microscopic investigation has proved that fifteen or twenty minutes after a sun bath the number of intracellular microbes increases rapidly, but at the end of several hours or of several days of exposure the phagocytes carry on vigorously their microbicidal work.

Mieres,[7] in the *Presna Medical*, Argentine, reports the results of heliotherapy in cases of tuberculosis of kidney or bladder, or both. The heliotherapy was combined with tuberculin treatment and he reports that it gave excellent results.

Use in Cutaneous Tuberculosis

Doufourt[8] uses the sun rays in cases of cutaneous tuberculosis and reports success. He removes the cheesy matter before applying the sun treatment, and emphasizes the point upon which the majority of his colleagues agree, that surgical aid is indispensable to render heliotherapy effectual, since the sun has no chance to heal the living tissues until the dead tissues are removed. In cases of lupus, pressure is used upon the affected region to keep out the blood which would otherwise absorb too many of the healing rays. A lens is also used in treating this disease to exclude the ultraviolet rays. Doufourt says that if a suspicious lesion responds to heliotherapy it is probably tuberculous, since syphilitic lesions do not seem to yield to this treatment.

Mayer,[9] in speaking of the value of heliotherapy, adds the following to the usual list of diseases benefited: bone and joint tuberculosis, tuberculosis of skin, mouth, glands, pleura, and peritoneum, with occasional success in genito-urinary cases, and in pulmonary tuberculosis.

Use in This Country

Simpson[10] speaks of the successful use of the Kronmayer lamp observed by him in cases of angioma in which x-ray, radium and carbon dioxid snow had previously

failed. He suggests that the danger of scarring is much reduced by using the lamp treatment. He says the lamp is most useful in psoriasis, and slow but good in lupus. The general sunlight baths have been used according to Rollier's methods by Webb[11] at Colorado Springs and, although he finds it good in bone, joint, or glandular tuberculosis, he is not as optimistic as Rollier.

Source of Success in Heliotherapy

The therapeutic value of light treatment, whether by natural or artificial means, has been clinically proved so definitely that there is little chance for argument as to its value, although there is some diversity of opinion as to exactly what diseases indicate this treatment. The question as to what element of the light accomplishes the results is something on which we have varying hypotheses but little proof. The heat rays, luminous rays, chemical rays are all credited with their special properties, which one or another advocate considers most beneficial. There are, however, two basic principles held forth as explanatory of the success of heliotherapy: one is that the ultraviolet rays are directly bactericidal; and the other, that what bactericidal action follows the use of light is simply the result of an increased metabolism and use of reserves, raising the general tone of the entire system, combined with the drying effect of treatments which are due to heat and air.

Sources of Ultraviolet Rays

The lamps used in artificial heliotherapy have for the most part been adapted to give unusual quantities of ultraviolet rays. On the other hand, the sun's rays have been recently used in the lowlands where, according to some authorities, the atmosphere has cut off the ultraviolet rays of the sun until their quantity is negligible. Rollier insisted that elevation and pure atmosphere are absolutely essential in order to be supplied with these rays.

The results of the use of artificial lights seem to have been as successful as the treatment by the sun itself, as experiences with it at the Finsen Institute and in a large number of places where either carbon arc lights or quartz mercury-vapor light are used, have proved. These lamps are planned to give a maximum proportion of ultraviolet rays and in some cases where used for whole body baths they have been supplemented by Mol in Holland, and Collins in Denmark by a surrounding ring of incandescent lamps because the original lamp was found not to supply sufficient heat for the comfort and well being of the patient. Those who use the artificial heliotherapy generally work on the theory that it is efficacious because the ultraviolet rays are directly bactericidal; at the same time the luminous rays are, of course, present in the light used, and hence the effect of the luminous rays or an effect other than directly bactericidal by the ultraviolet rays may exist.

Ray Bactericidal in Water and Milk

Experiments with various substances to prove the bactericidal value of ultraviolet rays have met with varying results. The great difficulty encountered is that the rays of short wave length have very limited power of penetration and can be completely cut off by even so slight a thing as a marked turbidity in water. Their ability to destroy bacteria in clear water has been demonstrated to such an extent that some cities in France use this method for purifying their water supply.

On the other hand, experiments in this country with milk resulted in the conclusion that colloids in the milk prevent the penetration of the ultraviolet rays to such an extent that the process is not practicable. Milk treated for a long time in extremely thin sheets and passed over a revolving drum did lessen in bacterial content, although the milk developed a peculiar taste after long exposure.

Penetrability of Human Tissues

Dausset[12] says that the different rays of the spectrum do penetrate the body if sufficient time is given, but all at different rates, and Wagner[13] says that it is a false assumption that the ultraviolet rays penetrate the surface only and that their penetration is greater than has been believed up to the present. He adds that the actinic rays of average length are strongly bactericidal.

Stimulate Phagocytic Action

Leriche[14] of Lyons says, in speaking of the treatment of war wounds, that the fluid exuding from wounds under treatment by sunlight was found upon microscopic examination to be full of microbes in suspension or leukocytes containing microbes. In comparing smears made before and after treatment he found the phagocytosis even more clearly exhibited. Cololian's remark on this subject has already been mentioned, namely that fifteen or twenty minutes after a sun bath he found the number of intracellular microbes increased but that at the end of several hours or several days of exposure the phagocytes carried on vigorously their bactericidal work.

Bactericidal Effect Indirect

The experiences of these men are typical of the reports of many, all indicating that sunlight, or arc light treatments are followed by distinct phagocytosis; but the question still remains whether the ultraviolet rays are directly responsible for this, or whether it is a secondary effect resulting from an increased metabolism.

Sonne[15] of Denmark, as a result of experiments made by him, thinks that chemical rays have very little to do with the therapeutic action of general light baths. Sunlight, arc light, mercury-vapor light, all have the property, he says, of heating the blood to a remarkable degree without heating the body tissues. It seems plausible to assume, therefore, that to this action their unmistakable therapeutic effect is due.

Dilbet[16] insists that the main therapeutic action of the sun consists in a reinforcement of the means of defense of the organism and that the rays of the sun do not act as do bactericides and antiseptics in the ordinary sense.

Martin,[17] in the report of a Committee on Phototherapy in November, 1918, says: "The action on metabolism seems to be the whole secret of the success in phototherapy."

Experiments at the Pasteur Institute

At the Institute Pasteur in France, de Laroquette[18] has contended since even as far back as 1911 that metabolic changes are the case. In the *Annales the L'Institute Pasteur* for 1918, he published the result of a series of labora-

tory experiments undertaken by him in order to determine the value of the bactericidal action of the sun's rays. The experiments include the effect on bacteria in air, in liquids, and in solids. He comes to these conclusions: "Sunlight is not bactericidal except with long, strong, direct insolations." It acts on dry surfaces and where drying and evaporation takes place. "White light," he says, "accomplishes more than light of any color, blue being next in value, but far behind the white light."

He considers that the luminous rays are the effective element and says that filtration to prevent the ultraviolet or infra-red rays make no difference. He also concludes that heat is an effective element, since in experiments where ice was used the bactericidal action was diminished. The bacterial power of radiation, he says, is in the chemical action and also in the dehydrating action of the rays. The death of bacteria in sunlight is due to a great absorption of energy which effects dehydration, and congestion of protoplasm. The chemical rays are the most effective because the most absorbed by the bacteria and surroundings. Heat rays penetrate, but filtration soon makes them too weak for action. All radiations are destructive or exciting for protoplasm, according to the dose taken.

As to the bearing of his experiments on heliotherapy, he says that heliotherapy has bactericidal action only for surface sores, burns, and skin affections, but it cannot directly affect lungs, bones, and deeper structures.

Since the effectiveness of heliotherapy in cases involving these parts has been clinically proven, the explanation must be in the biotic action of sunlight on living tissues, general and local, an exciting and energizing action whose therapeutic importance cannot be exaggerated, and which results in a superactivity of the circulation and functioning of the organs and an increase of their means of defense. Continuing, de Laroquette emphasizes that this idea of the limited bactericidal action of the ultraviolet rays and the high biotic action of the heat and luminous rays was contrary to general opinion in 1911, but, although not yet admitted generally, it tends to be accepted by well informed authors.

Chaput[19] showed the part played by heat and hyperemia. Dilbet[16] insisted on his view that bactericidal action of the sun is the result of reinforcement of the means of defense. Leriche, Sencert and Dilbet showed that most of the microbes found before treatments are extra-cellular and after treatment almost all within phagocytes.

He concludes that this new doctrine in regard to the effects of heliotherapy leads to many important applications in the practice of heliotherapy, among them the use of filters as in radiology for the dosage, and the graduation of local and general insolation, the therapeutic importance of this latter idea, the assured continuity of treatments in spite of the temperature and the seasons by the installation of glass-enclosed galleries, and the eventual supplementing of the sun in these sun parlors as in horticulture by artificial sources of heat and light.

The new method of sun treatment advocated by Lovett of Boston is of interest in this connection. He speaks of the successful use of the method by M. de Thézac in Brittany. The treatment he describes differs from the usual sun treatment in that a lens is used, double convex, twelve inches in diameter, and mounted in a long tube so that all the rays used in the treatment pass through this lens. Lovett speaks of the excellent results obtained in the use of this treatment on suppurating wounds, the discharge being lessened and granulations taking on a healthier appearance along with a diminished sensitiveness of the wound.

The interesting point about this treatment in connection with the idea advanced by de Laroquette in regard to the small value of the ultraviolet rays in heliotherapy is that, since ultraviolet cannot pass through glass, the rays surely do not penetrate a thick convex lens. In the use of heliotherapy with this technic it would follow that the ultraviolet rays are discarded altogether; still the treatments are of proved value, as their use on wounds has shown.

The experience of Pitcher[21] in regard to the value of the use of powerful incandescent bulbs is another bit of evidence for the value of the heat and luminous rays in light treatment. Pitcher has been working along these lines, he reports, for a long time and has waited until he felt absolutely sure of his ground before reporting on the subject. He bases his belief that the light can affect more than superficial areas on the fact that the blood supply of the internal organs is in practically all cases closely related to the surface blood supply of that part. Since the light causes marked hyperemia of the surface tissues, by circulation of the blood, any benefit derived from light treatments can be carried to the deeper organs.

He speaks of the use of a five hundred candle-power incandescent lamp, and keeps the light as near as possible to the surface treated, in order to assure depth of penetration; he considers the treatment of the greatest value in mastoiditis or acute inflammatory conditions of the throat and chest. Since the incandescent light is not of value as a source of ultraviolet rays, this treatment involves particularly the use of heat and luminous rays.

The efficacy of light treatment, whatever its explanation, has been established. The chief objection to it is the length of time required and the consequent expense this entails. The risks incurred in the treatment are very slight, being confined to danger to the eyes, which may develop a conjunctivitis if not protected by adequate shading, and the possibility of blisters and burns, which are never of a dangerously severe nature. Its use as a supplement or substitute to x-ray treatments has been suggested because of the greater safety of the sun and arc light treatments. A suggestion has been made that the only present means of rendering heliotherapy a factor of much weight among the classes of people generally most in need of cure for the diseases indicated, would be to have Government assistance in defraying the expenses and thus make it possible to have many sanatoriums located in localities and climates where the maximum benefit could be derived, and yet with such an arrangement that others than the wealthy could take advantage of a treatment which necessarily is prolonged.

Praises Japanese Medical Schools

Dr. Jacob Gould, who retires as the active head of Cornell University this month, has recently returned from Japan. In his address before the class who received the degree of Doctor of Medicine at Cornell this year he pointed out some of the wonders of medical science developed by the Japanese. A very close relationship is maintained between the medical school and the hospital in Japan. They are masters in sanitation. Their medical students are chosen by a selective process which develops the best material, and it is only after a most thorough examination that the student is permitted to proceed with his work.

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

EDUCATION IN INDUSTRIAL MEDICINE

A COMPLETE review[1] of existing facilities in colleges and in medical schools for the training or supplementary education of industrial physicians has been published by the United States Bureau of Labor Statistics. Included in the article also are descriptions of courses in public health and related subjects, development of industrial clinics separately or in connection with hospitals, medical colleges, and state and municipal departments. The article states that modern industrial medicine has received the endorsement of economists, sociologists, and physicians as one of the principal means upon which hope of securing better industrial and social conditions must be based.

The "new specialty," or "mass medicine" as it is frequently called, has been variously defined. Many physicians use the term industrial medicine as if its meaning were limited to the treatment of industrial accidents and occupational diseases, but this idea is rapidly giving place to a larger conception of its scope, based upon the growing recognition of industrial medicine, and particularly of that important part of it known as industrial hygiene as a very vital factor in preventive medicine. Perhaps the best definition is that which recognizes it as all branches of medicine and surgery in their application to the prevention and treatment of accidents and sickness in industrial workers. The term will here be used in this last sense, though the exactness of consistency with which it is applied to the curricula of the different institutions cited is not vouched for.

The study of specific poisons and diseases in relation to certain occupations is an old one, but it has never been a popular branch of medicine. In the last few years employers of large numbers of people have begun to estimate the advantage to themselves of retaining the services of special physicians to supervise the hygienic conditions in their plants and to attend their sick and injured employees, so that at present a considerable number of physicians are thus employed, while others are engaged in the care of Federal and other public employees. A few public clinics for the treatment of industrial accidents or diseases, or both, have also been established.

But, while such avenues have been opened for the practice of industrial medicine, physicians who wished to specialize on this subject have, up to the present time, found meager facilities offered for training for their work. The lessons of the war and of reconstruction have, however, drawn marked attention to economic waste through accident and ill health and to the rôle which industrial medicine can be made to play, by reducing these, in the adjustment of industrial and social problems. Very recently steps have been taken to provide adequate training in industrial medicine in a few of our educational institutions, while the subject is receiving more or less attention in a number of others.

After describing the specific courses in the Harvard University Medical School and the University of Cincinnati Medical School the article outlines the courses in medical colleges which include industrial medicine, namely, Rush Medical College, Ohio State University Medical College, University and Bellevue Hospital Medical College, Columbia University College of Physicians and Surgeons, Johns Hopkins Medical School, Detroit College of Medicine and Surgery, University of Michigan Medical School, Northwestern University Medical School, and Washington College of Medicine.

After describing the available facilities, the following conclusions are expressed:

A few educational institutions besides those mentioned offer work which approximates the minimum afforded by the ones named. Still others are planning more extended work along this line than has so far been attempted by them, but are not ready to make their plans public. Even among those mentioned, however, very few are giving any but the most general attention to the subject. Only a small proportion of the clinics or hospitals specializing on the treatment of industrial accidents and diseases are making a special study of diseases in their relation to occupational conditions.

That this apparent ignoring of the importance of industrial medicine is not due to any lack of public interest in general health conditions is argued by the multiplication in all parts of the country of clinics, dispensaries, and other means for safeguarding the public health and teaching general hygiene. Indeed, the country seems to be thoroughly aroused to the importance of conserving the public health, and partly awakened to a realization of the predominant rôle which preventive medicine must play in such work. But the extent to which preventive medicine is bound up with the conditions under which the workers do their work, the action of such conditions upon the physical and mental health of the workers, and the consequent reaction of the workers thus affected upon the community have apparently not yet made any strong appeal to the imagination or the sympathy of the public. The subject has not even made a claim, in any proportion to its importance, upon the attention of the medical profession.

The most plausible explanation of this latter fact lies in the slight encouragement which, in the past, has been given by educational authorities for the study of this branch of medicine. For no matter what degree of public or of other interest may be enlisted in the subject, the burden of practical accomplishment in industrial medicine rests with the medical profession. This view is stressed by authorities in the matter in replies received to the letters sent out by the Bureau. Dr. Emery R. Hayhurst of the Ohio State University says that the work included under the "rather new term 'industrial medicine'" does not seem to be attractive enough to the recent graduate medical students, and adds:

Our graduates (who have received the medical degree) seem all bound up with the idea of taking a year or two hospital work, and after that going into private practice. It has so far seemed impossible to instill the idea of "mass" medicine in our medical [post-graduate] students. On the other hand, our university students [sociological and other non-medical students] seem over-enthusiastic about the whole concept of "mass" medicine, hygiene, and public health.

Nor are the undergraduate medical students, in his

1. Monthly Labor Review, May, 1920.

opinion, attracted to the subject, as evidenced by the fact that none are taking the elective courses offered by the university. Additional evidence of this apathy toward the subject on the part of medical students is afforded by the failure of any students to enroll for the full course in industrial medicine offered this year by the University of Cincinnati, and by the small number of medical students enrolled in any of the elective courses in the subject offered by other institutions.

In this connection Dr. Hayhurst says:

This seems to be due to the fact that the curriculum specified by the Council on Medical Education of the American Medical Association, which is the standard for A-class medical colleges—to which some seventy-eight of the existing eighty-seven medical colleges in the country belong—is so filled with prescribed work as to allow little opportunity for undergraduate medical students to carry any electives. There is some question in my mind whether, in view of the socialization of medicine, the character of the prescribed work should not be modified by the Council on Medical Education so as to admit proportional training in medical sociology, medical economics, "mass" medicine, etc.

The result of the neglect of the subject by medical students is that industries are employing persons for industrial medical service who, it is said by industrial medical specialists, are not trained or especially qualified for the work and who, in consequence, bring discredit upon such service. Dr. Hayhurst thinks the most urgent feature of the situation at present is that of ways and means of arousing the interest of educational institutions in the subject, and he suggests, as a possible help in meeting the demands of the time for industrial physicians, the establishment of scholarships and fellowships in industrial medicine so as to encourage medical students to enter this field.

Now that a few of the more prominent medical schools are offering special courses in industrial medicine, and others are providing better facilities than formerly for training physicians along this line, there is ground for hope that a new interest may soon replace the apathy which has been displayed towards "mass" medicine by medical students. This hope gains its strongest force from the demand which is growing for the employment of well equipped and socially minded men as physicians in industrial plants.

AN INDUSTRIAL DENTAL DISPENSARY

By H. M. BREWER, D.D.S., Dental Director, National Cash Register Company, Dayton, O.

A REVIEW of the work of our dental department for the eighteen months just past but serves to strengthen our belief in the statement made by Sir William Osler that "There is not one single thing in preventive medicine that equals mouth hygiene and the preservation of the teeth." The grave complications we observe as the result of neglected mouths, the loss of time by the employees, and the loss of production to the company, only emphasizes the need of a better and more thorough dental education in the public schools.

It would be difficult to enumerate the hours lost to a company through the bad teeth of the employees. Many hours are lost through systemic disturbances which could be traced to bad teeth, but which are not so listed. If these figures could be accurately compiled, the result would be even more significant. It is not difficult to see that many hours of valuable time could be saved by the recognition and removal of the focus of infection from the mouth of the employees of any factory.

The equipment and personnel of the dental department of the National Cash Register Company differs in no way from that of any first class surgical dentist. Every employee has the advantage of laboratory diagnosis and advice that takes into account all factors, and the Department functions actively in the field of preventive medicine.

It is along these lines and the teaching of mouth hygiene and prevention that the dental dispensary of the National Cash Register Company is conducted. The work consists of examinations, first aid treatments, gum treatments, prophylaxis, extraction of diseased teeth and roots, x-ray diagnosis, temporary fillings, consultation, and advice. We distribute literature on the care of the teeth and give illustrated lectures to the employees. We do not do restorative dentistry; but when the teeth are examined, we give the employee a chart with every decayed tooth marked and urge them to go to a dentist at once and have the necessary work completed.

We work in close cooperation with the medical department, and this is absolutely essential if the best results are to be obtained. As Dr. Charles H. Mayo has so truly expressed it, "The next greatest step in medical progress in preventive medicine should be made by the dentists." The dental profession should accept this challenge by removing the focus of infection from the mouth of every patient whose resistance is low and whose family tree is dotted with rheumatic, cardiac, and other fatal lesions. Many physicians are abusing the theory of dental infection by indiscriminate condemnation of vital teeth that should not be extracted. Many dentists have recently expressed this complaint to me. It is right that the physician should send his patients to the dentist for the elimination of mouth infection, but the dentist should make the final diagnosis. Recently a physician of this city sent a patient to his dentist with five teeth marked for extraction. The dentist made a careful examination and found that all of the five teeth were vital and free from infection. By the use of the x-ray the trouble was found and eliminated. Had the advice of the physician been followed, five good teeth would have been sacrificed and the offending one left in the mouth. Close cooperation between the physician and dentist will eliminate this trouble.

Beginning January 1, 1920, a dental examination was

included with the medical inspection of every applicant in the factory of the National Cash Register Company. At the time of examination, the applicant is urged to have the mouth put in first class condition. If diseased teeth and roots are found, the applicant is asked to report to the Dental Dispensary at an early date and have them removed. All decayed teeth are marked on a chart which is given to the applicant so that he may know the true condition of his teeth.

We believe that the efficiency of the applicant will be increased by having the infection removed from his mouth

and his organs of mastication put in good condition. That a large percentage appreciate this is shown by the voluntary examinations that have heretofore been given in the dispensary and the report of the city dentists who have received the charts from the employees.

To show the relation of dentistry to medicine, a brief history is given of three interesting cases of dental infection which were treated in our Dental Dispensary with most gratifying results. Notice the loss of time, wages, and production that must necessarily accompany all of such cases in a factory:

A, age forty-seven years, was confined to his home for seven weeks with arthritis and failed to respond to any treatment. His physician advised dental examination. At the end of the seventh week he visited the dental dispensary. Both knees and ankles were affected. He could not get his left hand to his face and had very little use of right arm. Examination disclosed seventeen diseased teeth, which included many dead teeth and broken down roots. The remaining teeth were badly affected with pyorrhea. We advised extraction of all his teeth. Two teeth were extracted at this sitting and at subsequent visits all of the teeth were removed. After his second visit marked improvement was noted in his condition and at the end of two weeks he reported for duty. He was not entirely well, but his condition was such that he was able to do his work. His condition gradually improved and in six months he had gained thirty pounds in weight. The arthritis has not recurred.

teeth.
Remarks _____

B, age forty-two years, reported to the dental dispensary on Monday morning after being off duty two weeks on account of arthritis in the right shoulder which prevented use of the arm. We extracted the upper first bicuspid root on left side, the upper cuspid on right side, curetted sockets, and removed pus sacs from each. This employee reported for duty on Friday morning of the same week with pain entirely gone, having recovered excellent use of his arm.

C, age forty years. For a period covering many months this employee had been afflicted with rheumatic lesions which were especially troublesome in the lower extremities. At times, his condition was such that he worked under great difficulties and had to be favored in his work. Many days were entirely lost and during these attacks he required assistance to go up and down stairs.

Upon examination nearly all of his teeth were found to be loose with pyorrhea and there were many pus pockets. His teeth were extracted and in a few weeks the rheumatic lesions had entirely disappeared. He is now able to do any kind of the work required of him by his department.

These cases are typical of a great many which are encountered in the handling of medical and dental work in a factory of seven thousand employees. We have recently installed an x-ray machine to our equipment which will be used in the routine examination of employees. It will undoubtedly be of inestimable value in diagnosis.

*Date*_____

Dispensary Service Free

The service in the National Cash Register Dental Dispensary is entirely free to the employees and all visits are made on the time of the company.

The Dispensary was opened in May, 1918, with one equipment and one full time dentist. In July, 1919, another equipment was installed and another full time dentist employed.

A complete record is kept of all operations. For the year 1919, the work included. Examinations, 1,777; prophylaxis, 1,726; extractions, 1,685; first aid treatment, 1,173; gum treatments, 430; temporary fillings, 94; x-rays, 76; consultation, 166; miscellaneous, 1,183, making a total of 8,310 treatments.

At the present time we are engaged in an oral hygiene campaign for the children of the employees. These children attend the Saturday morning meetings in the N. C. R. schoolhouse, where they are given instructive talks on health habits. The teeth are examined with the purpose of acquainting the parents with their condition. In the examination of 900 mouths we found decay in 1,936 permanent teeth, the ages of the children ranging from six to fourteen years. This is conclusive evidence that parents must be awakened to the vital necessity of saving these six year molars and the other permanent teeth for their children. Prevention must begin with the children.

The field of industrial dentistry is large and does not stop with the work at the factory. Its messages are carried to the homes by the employees and its effects are far reaching. The number of industrial dental dispensaries are constantly increasing, and in a few years dental service will have an important place with the medical department of every large manufacturing and mercantile institution.

THE EXPERIENCE OF MEDICAL DEPARTMENT AT NITRO, W. VA.*

By J. A WATKINS, M.D., Medical Officer in Charge, Department of Industrial Medicine and Public Health, University of Cincinnati; Medical Director, Lunkenheimer Company, Cincinnati

THE manufacturing area was extensive, the transportation of the injured necessarily slow, and the character of the injuries and accidents, by reason of the manufacturing processes being carried on, was such that it was necessary to construct and equip in various parts of the plant five emergency stations. With one exception, these were similar, being designed to afford a few beds for temporary care of the severely injured, to administer emergency relief, to serve as dressing stations for old injuries, out-patient relief, and small drug and equipment dispensary. The termination of the plant's activities prevented a thorough trial as to the success of such methods of medical relief. One station had a capacity of forty beds and was used during the time the General Hospital was being constructed and equipped.

In all emergency work and redressings a standard method of treatment and procedure was determined upon and in general followed out. Each attending physician was assigned to a small dressing table on which were placed all necessary dressings and equipment for most cases. Several such units were in the dressing room. The patient was admitted by the record clerk, where pertinent data on the case were obtained. He was then assigned to a physician and, when taken care of, passed out by a different door. A large number of patients were thus satisfactorily handled in a short time.

Emergency Relief Measures

Difficulty was experienced with many workmen in rendering this relief. Though endeavors were made continually, and in many ways, to impress upon men the necessity of reporting to a physician promptly after sustaining an injury, regardless of its severity, many delayed until infection

*The fourth installment of an article on the experience of the medical department at Nitro, W. Va., published in successive issues of Modern Medicine, beginning in April, 1920.

had been contracted; others failed to report for dressing and continued care; while still others attempted to attend themselves. It was encouraging, however, to note that such undesirable practices were gradually abandoned.

The following table gives the number and classification of injuries, together with the number of infections treated:

Ambulance and First Aid

First aid activities of the Medical Department were directed along two lines of endeavor: (1) the acquisition and maintenance of suitable locations throughout the plant of first aid apparatus, equipment, and material. First aid boxes were constructed, equipped, and suitably housed in various localities in the plant and their location designated by a red light and prominent sign; (2) the instruction of the better informed employees, and particularly those occupying responsible positions about the plant, in standard and approved methods of procedure in rendering relief. Such instruction was given in lectures by medical officers, safety engineers, and by written communications from the Safety Department and the Medical Department. They dealt in the main with the control of hemorrhage, treatment of concussion, fracture, electric shock, the asphyxiation by gas and water, and the several particular industrial hazards met with in this plant. There were distributed about the plant, at suitable locations, ambulance stations to which, unless the particular case did not permit, injured men were taken immediately upon turning in the ambulance call. This did away with much confusion, and the ambulance was able to go directly and rapidly to a certain point to receive the patient. Correct records were kept from the time of the receipt of the ambulance call, of the driver, the medical officer accompanying, the time of its return, and disposition of the case. The type of ambulance used is discussed under the section of transportation.

Complete data on ambulance service would have been of value, but were lost by fire. The following are of interest, though incomplete. More than three thousand ambulance calls were answered. Twenty per cent of all calls were made during the first hour the men went to work, while 16 per cent of all calls were made during the last hour of work. The remaining 64 per cent were rather evenly distributed except for calls for sickness, as distinguished from injury, 90 per cent of sick calls coming in about midnight. The average time of making one call was twenty-four minutes.

The city dispensary was located in the center of the residential section of Nitro City. It was ninety feet long and forty feet wide, almost rectangular, and one story high.

There were a reception hall, office space for attending physicians, and rooms for the following divisions: drug dispensary, surgical clinic; eye, ear, nose, and throat department; gynecological, pediatric , and medical units. Toilets, with locker rooms adjoining, room for nurse's quarters, as well as a laboratory, a supply room, and a dental department, were provided. This dispensary proved to be of great value in offering medical and dental out-patient relief to dependents of employees at Nitro.

The dispensary handled 644 minor surgical cases; 7,201 medical cases, of which 2,224 were Flu, were treated, making a total of 7,845.

Wherever illness occurred in the family and it was not convenient or expedient, under the circumstances, for the patient either to report to the out-patient dispensary or to come to the hospital, a medical officer was detailed to call at the house. This system is not recommended, as the privilege was abused.

The isolation hospital consisted of two wards 180 by thirty-two feet, parallel with each other, and was situated about one hundred feet north of the group of five wards which flanked the north end of the General Hospital. These two buildings

East porch of the General Hospital, Nitro, W. Va.

were identical and, with the kitchen, formed an isolated unit.

It was desired to carry out and demonstrate some modern methods of procedure regarding the prevention of cross infection in hospitals. The success of these methods of procedure, however, depend so much upon the intelligence and training and, also, on the conscientious performance of duty and the scrupulous observation of rules by hospital attendants that, under conditions existing at Nitro, these methods were not deemed safe. A plan was adopted, therefore, which was as similar to that desired as was considered safe, that is, the grouping of similar infections in small six-bed wards.

During the period under discussion the service records of the isolation hospital show the following cases admitted and cared for:

COMMUNICABLE DISEASES OTHER THAN VENEREAL

Disease	*Admissions*
Diphtheria	6
Epidemic cerebrospinal meningitis	5
Erysipelas	6
Measles	27
Mumps	11
Pneumonia, lobar	18
Pneumonia, broncho	25
Scarlet fever	6
Smallpox	8
Whooping cough	3
Trachoma	45

VENEREAL INFECTIONS

Disease	*Admissions*
Balanitis	2
Chancroid	141
Epididymitis	59
Gonorrhea	1,663
Gonorrheal ophthalmia	1
Herpes genitalis	1
Inguinal adenitis	24
Prostatitis	21
Syphilis	328
Urethral abscess	3

The total normal bed capacity of the General Hospital was 520. The group known as the General Hospital was made up of the following units: One garage, one orderlies' quarters, one nurses' home, one superintendent of nurses' bungalow, one pharmacy, one administration building, one resident officers' bungalow, one dental, x-ray, eye, ear, nose and throat building, one receiving ward, one male nurses' quarters, four double wards, one maternity ward, one laboratory building, one operating pavilion, one commissary department building, two private room wards, one laundry and boiler room building, one mortuary, one storehouse, and two attendants' quarters.

This hospital was located at the terminus of the main road on the edge of the reservation. It had a frontage on this road of approximately one-half mile and ran back to a depth at its widest point of one thousand feet.

A detailed description of these units cannot be given here, though the accompanying illustrations give a good general idea of the layout. The

A Private ward of the General Hospital at Nitro, W. Va.

buildings were characteristic of the general construction of housing at Nitro, being one story frame and plaster structures. There was steam heat from a central heating plant; electric light and power were provided, and also gas light for use in emergency. The main corridor of the hospital, 880 feet long, ran north and south through the hospital area, and the various buildings comprising the hospital group were joined to this by communicating corridors.

A detailed discussion of the work of the General Hospital would be of little interest. It was constructed and operated for the same purpose and conducted in general in the same manner as an institution of similar character and size in any urban community. The buildings were on the whole the best constructed and finished of those at Nitro. The hospital was completely sup-

plied with the most modern equipment available. In organization and conduct an attempt was made to follow plans developed by several of our most successful institutions. The operation of this unit was, on the whole, I believe, satisfactory. This success was due largely to the work of the superintendent, Miss Ida Gilbert, of the American Red Cross.

A great disadvantage was the undesirable separation of units. This was, under the circumstances,—type of building, fire hazard and such conditions,—unavoidable. Difficulty was also experienced in obtaining satisfactory hospital personnel other than nurses and physicians.

In the Surgical Division 1,157 cases were treated. There were 197 major operations and thirty-four nose and throat operations. Fifteen obstetrical cases were handled.

The X-Ray Department was fully equipped in the most modern manner and most excellent results were obtained by the roentgenologist, Mrs. E. B. Liddle. Five hundred forty-eight plates and 1,005 observation were made. Very little therapeutic use was made of the facilities at hand.

Discussion of Surgical Cases

There were only thirty-seven cases of abscesses admitted to the surgical unit, including three of the foot and six of the hand. As no case of tetanus was recognized, it is significant that all puncture wounds were given antitetanic serum, 500 to 1,500 units.

There were eighteen cases of appendicitis, being about the proportion obtaining in most civilian communities.

There were very few acid burns serious enough to require hospital treatment, and only four cases of burns from explosions, none of which was severe. Steam burns were most numerous, ten in number, none fatal.

The contusions numbered 105, and lacerations of serious nature were admitted. The larger groups in this division are back muscles, scalp wounds, foot, ankle, and leg injuries.

The fractures attended were an interesting study, about 10 per cent of these being compound. Of these fractures, the bones of the lower leg and forearm were the most commonly involved. The fibula was broken more often than the tibia. There were three cases involving both the ulna and radius, all in the left arm, one being treated with bone graft, one by open reduction, and one by extension. The ultimate results were good. Among the six fractures of the skull there were no deaths, though one case became comatose twelve days after injury and demanded a decompression for increased intracranial pressure. A large number of those examined at the employment office had hernias, though only thirty-four cases were operated upon. No strangulated hernias were taken care of by the surgical unit, but there were five incarcerated hernias, and eight hernial sacks which had become irritated by pressure of trusses. The remainder were hernias developing more or less suddenly, causing the patient to suffer discomfort or pain in the region of the hernia whenever exertion was more than usual. One clean hernia case became grossly infected after operation.

An unusual accident was "sand smothering." This patient was assisting in the dumping of a car loaded with sand. Slipping off the edge of the hopper, he was quickly covered with fine sand, and not until he was drawn from the small end of the hopper about two minutes later was it considered that he might still be alive. His nose, mouth, and upper respiratory apparatus contained a considerable amount of sand. For about three days the patient at times brought up sand from his trachea, sometimes mixed with blood. He suffered no other injury.

Details of Medical Service

The cases referred to the medical service by the receiving ward numbered 3,537; of these, 3,107 were diseases of the respiratory tract, only seventy-six of which were other than influenza or its complications; 268 involved the gastroventral tract. Sixteen were cardiorenal diseases, while of the remaining 79, 21 were malaria, 19 arthritis due to various causes, and 26 acute alcoholism. One case of heart block was admitted. The ventricular pulse rate varied between 30 and 40 per minute.

The Laboratory Division

This part of the General Hospital was small but well equipped, and was of great assistance to the work at hand. More than twelve thousand reports were made upon request by this department, covering the entire field of laboratory activities.

Scope of Dental Division

A dental division was established, both with the view to offering relief in neglected cases and of encouraging better oral hygiene habits and prophylactic practice among workmen and their families, especially among the school children. A well qualified dentist, having two assistants, was placed in charge. Relief and advice were available at the emergency hospital, at the main dental clinic of the General Hospital, and at the civic center dispensary. As has been the observation of others, a large percentage of persons required dental advice or service. This division handled 3,044 patients for thirty different complaints.

(To be continued)

FEE SCHEDULES UNDER WORKMEN'S COMPENSATION

In Ohio, after prolonged discussion and conference a new fee schedule was established by the Industrial Commission of Ohio, substantially increasing medical and surgical fees under the Workmen's Compensation Act. This schedule will be of widespread interest to physicians for the reason that the Ohio Compensation Act is universal and compulsory and all industrial accidents come within its scope. The *Ohio Medical Journal* states, "The new fee schedule is the result of the spirit of cooperation which has existed between the industrial commission and the headquarters of the State Medical Association."

A number of physicians worked with Dr. T. R. Fletcher, chief medical examiner of the Industrial Commission, including Dr. J. T. Baldwin, president of the State Association; Dr. C. D. Selby, Toledo; Dr. W. P. Chamberlain, Cleveland; Dr. J. R. Beiter, Canton; Dr. R. H. Wilson, Martin's Ferry; Dr. Robert Carothers, Cincinnati; and Dr. George P. Dale, Dayton.

Believing that the fee schedule thus arranged would be of special interest to the readers of MODERN MEDICINE, we reprint the detailed schedule.

Miscellaneous

Minor injuries (first dressing) day at office	$ 3.00
Minor injuries (first dressing) home or hospital	5.00
Minor injuries (first dressing) night (9 P. M. to 6:30 A. M.)	7.00
Subsequent treatment at office	1.50
Hospital visit	2.00
House call	3.00
Administration of anesthetic by physician (minor operation)	5.00
Administration of anesthetic by physician (major operation)	10.00
Administration of anesthetic by hospital anesthetist	5.00
Assistant to surgeon (physician) minor operation.	5.00
Assistant to surgeon (physician) major operation.	10.00
Removal foreign body eye (ordinary)	2.00
Suturing small cuts or lacerations, office	5.00
Injection antitetanic serum (including cost of the serum)	5.00
Plaster casts (including material and depending on location)	$5.00 to 50.00
Wassermann examination	5.00
Blood examination	5.00
Urinalysis (chemical)	2.00
Urinalysis (microscopical and chemical)	5.00

Special Operations

Laparotomy—minimum fee with after care	100.00
Note.—On account of vast difference in such cases, claim for services rendered should be based on special correspondence.	
Herniotomy—single (including after care)	75.00
Herniotomy—double (including after care)	100.00
Tendon suture	25.00
Reducing hernia by taxis and after care	5.00
Note.—Truss will be paid for upon presentation of statement showing cost.	

Dislocations

Flat rate including reductions and subsequent treatment.

In a case of more than one dislocation, the fee shall be the major one plus an additional 50 per cent of the fee prescribed for each of the others herein classified.

Shoulder	$ 35.00
Clavicle	50.00
Elbow	50.00
Hip	50.00
Knee	50.00
Patella	5.00
Ankle	25.00
Finger	10.00
With 50 per cent additional for more than one.	
Toe	5.00
With 50 per cent additional for more than one.	
Lower jaw	10.00

Fractures

Flat rate, including reduction and subsequent treatment.

In a case where multiple fractures occur the fee shall be the major plus an additional 50 per cent of the fee prescribed for each of the others as herein classified.

Humerus	$ 75.00
One bone of the forearm	50.00
Both bones of the forearm	75.00
Carpal bones, one or more	15.00
Femur	100.00
Tibia	50.00
Fibula	25.00
Tibia and fibula	75.00
Patella, with operation	100.00
Patella, without operation	50.00
Os calcis	30.00
Astragalus	30.00
Tarsal other than os calcis or astragalus	15.00
Rib—single or multiple	10.00
Nasal bones	10.00
Phalanx, metatarsal or metacarpal	15.00
With 50 per cent additional for additional fractures.	
Pelvis—a proportionate fee on the above basis will be determined according to conditions present	.....
Coccyx, without operation	10.00
Coccyx, with operation	35.00
Lower jaw (not including dental work)	40.00
Upper jaw—non-operative	15.00
Upper jaw—operative fee determined according to conditions	.....
Clavicle	50.00
Scapula	40.00
Skull, non-operative	25.00
Skull, operative	100.00
Vertebrae—minimum	50.00
Note.—On account of vast difference in such cases, claims for additional services should be based on special correspondence.	

Compound fractures—An additional charge of 50 per cent may be added in infected compound fractures.

Wiring or plating—An additional charge of 50 per cent may be added when it is necessary to perform open operation. This is not in addition to amount allowed for compound fractures.

In unoperated complicated fractures in which union is not taking place within ninety days, and additional charge may be allowed at the discretion of the Industrial Commission.

Amputations

Flat rate including amputation and subsequent treatments.

Note.—The minimum fee in the items under this section are intended to be applied in those cases where the injuries were so serious that death resulted within one week following the operation. The maximum and intermediate fees are intended to cover more extended subsequent attention.

In cases of more than one amputation, the fee shall be the major plus 50 per cent of each of the others as herein classified.

Hip	$100.00	$150.00
Leg, at knee or above	75.00	125.00
Foot, ankle or below ankle	50.00	75.00
Arm, at shoulder joint	75.00	100.00
Hand, wrist, forearm or arm	50.00	75.00
One toe or finger	.....	25.00
With 50 per cent additional for more than one.		

General Information

Reconstructive work to be paid for must be taken up with the Industrial Commission and fee decided upon prior to operation. This rule will be rigorously enforced.

A proportionate fee will be paid by the Commission in any case terminating fatally within a few hours.

In plastic operations and all other surgical procedures not included in this schedule, fees will be paid in keeping with other fees outlined.

In the event one physician renders first aid and the claimant is subsequently referred to another physician for completion of treatment and after care, due to lack

of proper facilities or for any other reason, a fee will be paid by the Commission in keeping with the services rendered and in addition to the flat rate schedule. In all cases it is incumbent upon the physician to set forth clearly the services rendered.

Itemized statements shall be furnished upon request of the Commission, if fee is claimed in excess of rate as given above.

In minor injuries daily dressings will not be paid for unless the necessity for same is clearly set forth.

Fees shall not be approved for the services of more than one attending surgeon over the same period of time. This does not apply to consultant, anesthetists, assistants, or cases where the need of an ophthalmologist is clearly shown.

Fees for high frequency or other electrical treatment will not be approved unless specifically authorized by the Commission.

Extra fees for dressing material and drugs will not be approved except in unusual cases wherein an extraordinary amount of such material or drugs is used. In such cases, the material or drugs used will be paid for at cost.

Diseases of the Eye

Note.—These fees will be approved only to physicians of recognized standing whose practice is strictly limited to eye, ear, nose, and throat work.

1. Foreign body of cornea and sclera:	
(a) Attached to cornea or sclera but not imbedded	$ 2.00
(b) Simple imbedded	3.00
(c) Difficult or complicated—including cases requiring use of magnet	$5.00 to 15.00
2. Cauterization of corneal ulcer	5.00
3. Laceration of lids or "conjunctiva" requiring suturing	10.00
4. Extraction of foreign body from inside the eyeball with or without magnet	$50.00 to 75.00
5. Treatment extensive burn of the cornea (initial treatment)	$5.00 to 10.00
6. Penetrating wounds:	
(a) Not requiring surgical interference	10.00
(b) Requiring surgical interference (ex.—lacerated cornea with prolapsed iris requiring iridectomy)	50.00
7. Enucleation of eyeball (flat rate including after care):	
(a) Simple enucleation	50.00
(b) Implantation operation	75.00
8. Plastic operation on lids	$50.00 to 100.00
9. Extraction of traumatic cataract (flat rate including after care)	100.00
10. Discission of capsule (flat rate including after care)	50.00
11. Operation on pterygium (flat rate including after care)	25.00
12. Consultation	10.00
13. Complete ophthalmological examination and report	10.00
14. Complete ophthalmological examination and report for court purposes and only upon order of the Commission	25.00
15. Refraction	$5.00 to 10.00
16. Office calls	2.00
17. Home calls	4.00
18. Hospital calls	3.00

Note.—Inasmuch as this schedule is to be used by specialists of recognized standing, it will be necessary for the specialist to indicate on fee bill filed that his practice is limited solely to diseases of the eye, or the eye, ear, nose, and throat, and that he is recognized as a specialist along these lines in the community in which he practices.

Rules on X-Ray

The following rules and schedule of fees will govern the making of x-ray examinations of injured workmen protected by the Workmen's Compensation Act and payment thereof:

(1) X-ray examination may be made upon request of the attending physician in any case where is can be clearly shown that such an examination is essential in the diagnosis or treatment of an industrial case.

(2) It is understood that before the Industrial Commission may assume responsibility for such examinations the claimant shall make application to the Commission, properly certified to by the employer, and recognized by the Commission as a compensable claim.

(3) A fee of $10 will be allowed for x-ray examinations and must not be exceeded except under the following conditions: (a) An additional charge of $5 will be allowed if an examination of two or more parts of the body is necessary. (b) A fee of $5 will be allowed for subsequent examinations if such are necessary. (c) An additional fee of $5 will be allowed for the accurate localization of a foreign body in the eye.

(4) A written report and fee bill accompanied by prints or films in duplicate must be on file with the claim before charges will be approved. Reports of x-ray examinations should give the number of the claim, name of the claimant examined, name of the employer, name of the attending physician, date of examination, date upon which the injury was sustained, a complete interpretation of the examination made, and should be signed by the roentgenologist making the examination.

INDUSTRIAL HEALTH LITERATURE

The National Safety Council recently issued the following brief summary of important sources of health information for industrial work:

A good deal of the most valuable information on this subject has come to us from our own members in the form of reports describing the well organized health supervision of their respective employees.

Another valuable source of information is the U. S. Public Health Service, Washington, D. C., which has issued many popular publications on such subjects as studies of the medical and surgical care of industrial workers, industrial hygiene, common drinking cups, common towels, communicable diseases, disinfectants and disinfection, mosquitoes, rat extermination, sanitary legislation, sewage disposal, venereal diseases, etc. The *Public Health Reports* issued weekly by this same government department also contain, in each issue, one or more leading articles on some timely subject relating to hygiene, sanitation, or public health. Other features of each issue are the statistical information relating to the prevalence of disease throughout the United States and sanitary legislation including state laws, city ordinances, and court decisions.

The British Government has also issued invaluable "blue books" on the health of munition workers, industrial health and efficiency, industrial fatigue, etc. These British publications may be obtained from H. M. Stationery Office, Publications Branch, Imperial House, Kingsway, London, W. C. 2 England, at a nominal charge. Many of the states and larger cities also issue publications containing worthwhile health articles.

Such magazines as the following devote much space to industrial health problems: *American Journal of Public Health*, Chicago; *Hospital Management*, Chicago; *The Journal of Industrial Hygiene*, New York City; MODERN MEDICINE, Chi-

cago, and *The Modern Hospital,* Chicago, Ill.

Our richest source of industrial health information is the proceedings of the Health Service Section of the National Safety Council and the health service bulletins issued by the Council. Standard books on health and proceedings of various health associations are also used.

PRONE PRESSURE METHOD OF RESUSCITATION

THE prompt and efficient use of the prone pressure method of resuscitation from electric shock has brought back to life many persons who were apparently dead. The manipulations are not to be stopped or interrupted until the patient breathes or *rigor mortis* sets in. The rules follow:

(I) Free the victim from the circuit immediately.—Quickly release victim from the current, being careful to avoid receiving a shock. Use any dry non-conductor (rubber gloves, clothing, rope, board) to move either the victim or the conductor. Beware of using metal or any moist material. If necessary, shut off the current.

(II) Instantly attend to the victim's breathing.—As soon as the victim is clear of the conductor rapidly feel with your finger in his mouth and throat and remove any

Fig. 1. The patient is to be placed at once in this position.

foreign body, such as tobacco or false teeth. If mouth is tight shut, pay no more attention to it until later. Do not stop to loosen the patient's clothing, but immediately begin actual resuscitation. Every moment of delay is serious. Proceed as follows:

(a) Lay the patient on his belly, one arm directly extended overhead, the other bent at elbow and with face to one side, resting on the hand or forearm, so that nose and mouth are free for breathing (Figure 1).

(b) Kneel straddling the patient's hip bones or opening the pants pockets; place the palms of your hands on the small of the back, with fingers spread over the lowest rib, the little finger just touching the lowest rib, the thumb alongside of your fingers, tips of fingers just out of your sight, as in Figure 1.

(c) While counting one, two, and with arms held straight, swing forward slowly so that the weight of your body is gradually but not violently brought to bear upon the patient. (Figure 2.) This act should take from two to three seconds.

(d) While counting three, immediately swing backward so as to remove the pressure, thus returning to the position shown in Figure 3.

(e) While counting four, five,—rest.

(f) Repeat deliberately twelve to fifteen times a minute the swinging forward and backward—a complete respiration being accomplished in four or five seconds. Time with your own breathing.

(g) As soon as this artificial respiration has been started, and while it is being continued, an assistant should loosen any tight clothing about the patient's neck, chest or waist. Keep patient warm.

(2) Continue resusciation, if necessary, four hours or longer, without interruption until natural breathing is restored, or until a physician declares *rigor mortis*—stiffening of the body—has set in. If natural breathing stops after being restored, use resusciation again.

Fig. 2. The weight of the body is gradually brought to bear on the patient.

(3) Do not give any liquid by mouth until the patient is fully conscious. Place ammonia near the nose determining safe distance by first trying how near it may be held to your own. The assistant should hit the patient's shoe heels about twenty times with a stick or something similar and repeat this operation every five minutes until breathing commences.

(4) Give the patient fresh air, but keep him warm. When patient revives keep him lying down and do not raise him. If doctor has not arrived give patient one teaspoonful of aromatic spirits of ammonia in a small glass of water if he can swallow.

Fig. 3. While counting three return to this position.

(5) Carry on resuscitation at closest possible point to the accident. Do not move patient until he is breathing normally without assistance. If absolutely necessary to move he should be placed on a hard surface, such as a door or floor for conveyance. Do not stop or interrupt resuscitation for an instant.

(III) Send for doctor.—If alone with victim, do not neglect immediate and continued resuscitation in order to call a doctor; start at once, the first few minutes are valuable. If other persons are present, send one of them for a doctor without a moment's delay.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

GARBAGE DISPOSAL AND THE PUBLIC HEALTH

OUR viewpoint in regard to the proper disposal of the solid wastes of the city has passed through three distinct phases during the past two decades.

Twenty years ago the general trend of opinion among sanitarians was distinctly in favor of the incineration of mixed refuse in the English type of high temperature destructor. Cremation in American furnaces without forced draft never had any valid scientific backing; but incineration at high temperature, as exemplified at Westmount, just outside of Montreal, and, later, at West New Brighton, Staten Island, was shown to be an efficient and inoffensive process. All the earlier reduction plants were operated under contract with private companies which exacted payment of considerable bonuses, so that from a financial standpoint cremation and incineration, as practised at that time, were almost equally costly. On esthetic grounds incineration was generally preferred, in the belief, somewhat cynically stated by Dr. S. H. Durgin, that "reduction is always a nuisance, and cremation is not always a nuisance."

Gradually, however, a change took place in the estimate which was placed upon the respective merits of incineration and reduction. On the one hand, the operation of incinerating plants, while most satisfactory from a sanitary standpoint, proved even more costly than had been anticipated, and nowhere in America was any serious attempt made to reduce this cost by utilizing the heat energy generated, as had been done in British towns. On the other hand, the nuisance from reduction works was somewhat reduced by improved construction and methods of handling; and, above all, experience with municipal operation of reduction plants—as at Columbus—showed that this process should really yield a substantial profit instead of constituting an item of expense. The private companies, in response to the knowledge acquired by this municipal experience, were forced to make contracts on a new basis. In New York, for instance, when the contract for garbage disposal was renewed, the company paid the city twenty-five cents a ton instead of receiving a bonus of thirty cents a ton, as it had done before. Six years ago, it seemed that, in spite of the danger of local nuisance, reduction was the method of choice for all cities of considerable size, on account of its material economic advantages.

The economic reactions of the war have, however, upset all calculations here, as in so many other fields. Complaints of nuisance due to the reduction plant have continued; but the large revenues once derived from this process have disappeared. The cost of labor and fuel and equipment tends to outstrip the value of grease and tankage, and between 1916 and 1919 the economies effected by the housewife reduced the available grease content to be extracted from garbage from sixty-seven to fifty pounds per ton. In Bridgeport, Conn., the city has been forced to take over a reduction plant which the contracting company could no longer operate, even with a heavy bonus. In New York both reduction plants are closed down and garbage is being dumped at sea.

The pendulum today swings back to a more primitive method of disposal than either incineration or reduction, to the simple procedure of feeding the garbage to hogs. Many small cities, and a few large ones—Worcester and Providence, for example—have clung persistently to this practice; and it has appealed particularly to the practical shrewdness of the city fathers of New England. Experience has shown that hog farms may be conducted so that they shall not be a source of offense; and that such farms may constitute a very considerable source of revenue. Recent contracts entered into at Newark, N. J., and Baltimore, Md., with steps toward the establishment of hog farms at Washington, D. C., indicate the rapid growth in favor of this method of handling the garbage problem, even for cities of large size. At all three of these cities hog feeding has been adopted after actual experience with reduction or careful study of its possibilities. The Baltimore plant will be the largest piggery in the world, supporting fifteen thousand hogs, with an estimated return to the city from 55,000 tons of garbage of $165,000 a year. Where the method of feeding is applicable and can be satisfactorily adapted, cost of disposal, sanitation, the utilization of its economic content are all served. Of the sixty-six cities estimated as having over 100,000 population in 1916, twenty cities, or about 30 per cent have this method of disposal.

A particularly interesting phase of the situation lies in the fact that this method of garbage disposal is urged not only as a financially economical one, but as a procedure of importance to the general public weal as a method of conserving foodstuffs. The United States Food Administration lent all its influence during the war to the furtherance of the production of pork from municipal garbage. In 1918 alone forty cities of over ten thousand population adopted the feeding method of disposal, which should provide from fifteen to twenty million pounds of pork *per annum*.

Thus we find that garbage, considered in the early days of the filth theory of disease, as a health deficit to be disposed of as inoffensively as possible, becomes a health asset, an important contribution to the food resources of the nation. EDITOR.

SALIVA-BORNE INFECTIONS: THEIR TRANSMISSION THROUGH EATING UTENSILS

By JAMES G. CUMMING, Lieutenant Colonel, Medical Corps, United States Army; CHARLES B. SPRUIT, Captain, Medical Corps, United States Army, Vladivostok, Siberia; and FRITZ A. REUTER, Captain, Medical Corps, United States Army, Washington, D. C.

MILLIONS have been expended for the purpose of providing pure water supplies, thereby protecting the populace against the intestinal-borne infections. This protection has given results which are wholly satisfactory and prove the efficacy of this line of attack. Can a similar expenditure, if properly directed, meet with as encouraging results in the protection of the populace against the saliva-borne infections?

Health education has proceeded to a point where it is no longer necessary to argue the advantage of personal hygiene. Its value is conceded even when it is not uniformly practised.

But individual habit does not afford protection against mass action, and the possibility of high exchange of infectious organisms in eating houses makes essential their sanitary control.

So simple a measure as boiling water in dishwashing would eliminate one of the major avenues of transmission of diseases which exact in early deaths a far greater toll than can be charged to any other group of infections.

Today, the saliva-borne infections cause the majority of deaths. Chief of these are tuberculosis and pneumonia. Since the toll in early deaths from these diseases is far greater than that from any other group of infections, it would be justifiable to make a concerted attack against these alone; for if this attack is properly executed and directed against the major avenue of transmission, there will be an immediate reduction in the transmission rate, and an automatic lowering of the mortality rate. In addition, it is to be pointed out that successful control of the above mentioned infections, through blocking the major avenue of transmission, will automatically control the many other saliva-borne infections. One cannot well conceive of the different saliva-borne infections as having different routes of travel from the infected to the non-infected, so that preventive measures which apply to one of these infections should be equally applicable to all. Preventive measures applicable to the control of tuberculosis will be applicable with equal force to the control of pneumonia, measles, or meningitis. These control measures for this group of infections must be directed against the major avenue of transmission. Our chief object must be to reduce the transmission rate by as great a percentage as is possible of accomplishment. This reduction in the transmission rate accomplishes two important factors in preventive medicine: (1) it reduces the sick rate, and (2) what is of greater importance, it reduces the carrier rate. In order that this may be done our greatest effort must be directed against the major avenue of transmission. There will then be few cases, but few sources, and but few deaths.

It is interesting to note the evolution of medicine from the preventive viewpoint. For centuries the chief object has been that of cure. During the last few decades, much attention has been paid to actual prevention. In the main, prevention of the saliva-borne infection has consisted in the isolation of the sick and the carriers, the quarantine of contacts, the use of the cubicle and the mask, and the vaccination of susceptibles. In many cities and in the Army, these preventive measures were carried out with great care; but, in view of the high mortality rate from this group of infections in cities, and the much higher rate in the Army, where the regulations were more strictly adhered to, it is apparent that the *modus operandi* was wholly inadequate to accomplish the desired results. It is doubtful if these preventive measures had any marked beneficial effect in prevention. Why? Because the principles on which these preventive measures were built are epidemiologically unsound. They are delayed reactions; they only deal with the individual after infection has occurred, and ineffectually attempt to control transmission through an attack against the minor avenues of distribution.

On the basis of "theory of case and source elimination," it has been pointed out that the effectual control of the saliva-borne infections depends on an attack through the major avenue of distribution only, and that then the minor avenues become insignificant and of no practical importance. In view of this principle, and the added fact that there are always many unrecognized

cases and carriers which act as sources, it at once becomes evident that our control measures of the past have been of but meager value in preventing transmission.

It is not the identification of cases and carriers and their isolation which we should aim at—this is delayed or tardy reaction—but rather our aim must be to prevent these cases and carriers. We must not get away from the epidemologic fact that in the saliva-borne infections, the proportion of carriers to cases is very great; that the carrier state persists for a considerable period; and that the large percentage of carriers results from the wide prevalence of these infections. In view of this consideration, is it not obvious that adequate control through the identification and isolation of the carrier is fraught with many difficulties and is of practically no value in ultimate and successful control? How, for instance, would we succeed if we were to attempt to control tuberculosis by such a procedure? The process would necessarily have to be continuous through many generations, and there would be no immediate reaction in reducing the transmission rate. The procedure is impossible in measles, influenza, and a number of other diseases of unknown cause, and has been wholly wanting in the experience of recent epidemics. The ultimate and successful control of the saliva-borne infections—their prevention in epidemic form—cannot, then, depend upon the control of the animate—the individual carrier, as maintained by Flexner[1] but rather our reliance must be based on the principle of applying sanitary measures on a wide scale to intermediate inanimate object carriers. This must be universal prevention; it must apply to all alike,—both the carrier and the non-carrier. The populace must acquire the habit of practising those measures which aim for universal prevention. These measures should not be instituted at times of threatened epidemics with the view of attacking them in their incipiency, but they must be continuous and of a habit forming nature. These preventive measures will necessarily be directed to the control of inanimate objects conveyors of infection, and not alone to the animate or original source of the infection.

Control Through Mass Action

If, then, the major avenue of transmission through inanimate objects is closed by universal mass action, by habit action, the importance of the animate fades into insignificance. The carrier is no longer a source of new infection. The problem is no longer one which deals with the individual but rather with a blocking of the major avenue of distribution through the inanimate.

Just as in the insect-borne diseases the intermediate insect carrier must be determined, then controlled and, finally, eradicated, so also in the saliva-borne infection the intermediate inanimate object carriers must be determined and then controlled, not necessarily by eradication as in the case of insects, but by the application of appropriate and practical preventive measures which block transmission through these objects. It is not the treatment of the sick, the identification of the carrier, nor the isolation of the contact, which will solve the problem of saliva-borne disease mortality, but it is the immediate reduction in the transmission rate which is of paramount importance in the prevention of sickness and the saving of lives. This reduction can be accomplished only by a determination of the major avenue of distribution and the universal application of a practical procedure which will break one or more links in the chain of transmission.

It has been our aim in the recent epidemics in the Army and the civil population to make a study of the avenues of transmission of the saliva-borne infections and to determine the relative importance of these several avenues of distribution. It was appreciated that more accurate knowledge as to the transmission was necessary for successful control. It was necessary to seek out the avenues both by field observation and laboratory research and, having determined the major avenue of transmission, it would then be possible to block this avenue and thereby reduce the transmission rate. By reducing this rate, there would be a reduction in cases, a reduction in carriers, and a reduction in sources.

Contrary to the generally accepted theory that this group of infections was air-borne, it was our impression that they were spread by indirect contact, and chiefly through the contamination of intermediate inanimate objects. As immediate conveyors to the oral or nasal cavity then, hands and eating utensils would be the chief offenders. Our preventive measures would therefore necessarily deal with the inanimate and not the animate, for it is obvious that inanimate conveyors make up the bulk of transmitting avenues. Furthermore, it would be folly to attempt through control of the individual to prevent contamination of these objects, for such contamination is inevitable.

In a previous report[2] it was pointed out that in the civil population the use of machine washed dishes gave a protection against influenza of 85 per cent. It was reported later[3] that in public in-

1. Flexner: Epidemiology and Recent Epidemics, Jour. Am. Med. Assn., 1919, lxxiii, No. 13.

2. Lynch and Cumming: The Distribution of Influenza by Indirect Contact: Hands and Eating Utensils, Am. Jour. Pub. Health, January, 1919.

3. Cumming: Influenza-Pneumonia in 370 Public Institutions as Influenced by Dish Washing, Am. Jour. Pub. Health, November, 1919.

stitutions having a population of 252,186 the use of machine-washed dishes gave a protection against influenza of 75 per cent. In still another report[4] it was shown that the use of boiling water for washing mess kits reduced the morbidity by 80 per cent and the mortality by 88 per cent. Although it is not the purpose of this paper to discuss mess sanitation among troops, it might be well to point out that the epidemiologic studies in the Army gave us definite information which was later applied to the studies of transmission in the civil population as here presented.

In the Army, warm mess kit wash water was the chief intermediate conveyor. From this central focus the infection radiated by the hand and mess kit avenues of distribution. This avenue is a five link chain[4] and the second and fourth links are double. These double links and the centralization of the infection, both of which were common to army messing, account for the high case rates and the explosive outbreaks of the saliva-borne infections in these groups of individuals. In the Army, as repeatedly shown, preventive measures consisted in control of the inanimate conveyors—the use of boiling water for washing mess kits. Of all preventive measures this one gave the highest degree of satisfaction and, since it reduced the case rate by more than 80 per cent, it may be concluded that the major avenue of distribution of saliva-borne infections in the Army was through the unsanitary method of washing eating utensils.

Parallel in Civil Population

Having in mind these epidemiologic considerations as applied to troops, one might ask whether or not there is a parallel avenue of transmission in the civil population. Let us repeat that in the Army the major avenue of transmission was a five link chain; that the immediate conveyors—the second and fourth links—were double and that these double links, hands and eating utensils, and the moistened state of the intermediate link, the wash water, account for the highly explosive nature of the outbreaks, especially that of influenza. In the civil population, there is a five link chain, but this is through dry inanimate objects which many people handle and by the hand to mouth route of travel. This is not the major avenue of distribution and is probably responsible for a small percentage of transmissions; but among civilians, we have a three link chain which parallels the five link chain in the Army. This chain of distribution is through eating utensils which are washed by unsanitary methods. The eating utensils of the case or the carrier become contaminated with saliva which is laden with infection. These utensils are washed in only warm water; they are not disinfected, and many infectious organisms still adhere to them after completion of the washing process. This is only a three link chain; the two end links are moist which makes for facility of transmission from the oral cavity of the donor to that of the recipient. The eating utensils are used for only one purpose; there is a great exchange of these from meal to meal between the members of the messing group and furthermore, they actually enter the mouth. In a former report[5] it was shown that by the usual hand method of washing only 30 per cent of tubercle bacilli were removed from eating utensils used by tuberculosis individuals.

If tubercle bacilli still adhere to utensils after they are washed, it is reasonable to assume that this finding holds true for the many other saliva-borne infections; in fact, this had been shown to also be the case with the group of pneumonia producing organism.[6]

In the Army camps the chief focus of distribution for any saliva-borne infection as, for instance, influenza—was the company mess kit wash water. All men of the company came in contact with this perfectly centralized focus, with the result that susceptibles readily became infected. The facility of transmission and the centralization of the distributive foci are the factors responsible for the explosiveness of epidemics in the camps. The susceptibility of the age group is not included as a factor in determining the degree of explosiveness because, as has been shown,[4] even though there may be a large percentage of susceptibles in a group, an epidemic may be prevented by the application of modern sanitary precautions.

We have pointed out the parallel in the major avenue of transmission for the Army and the civil population, and have indicated that this avenue in the former group was more prolific than in the latter. Have we then similar foci of distribution in the two groups? As a result of our epidemiologic studies we believe that the public eating place is the most highly centralized primary focus of distribution in the civil population. Since these foci for the civil population are not as highly centralized as those for the Army, and since the avenues of distribution are less prolific in the former group than in the latter, we have an explanation of the more highly explosive character of the virus epidemic in the Army than in the civil group.

On the basis of the importance of eating utensils as the major avenue of transmission and of

5. Cumming: Can The Tuberculosis Transmission Rate be Reduced? Jour. Am. Med. Assn.

6. Cumming and Spruit: Transmission of the Pneumonia Producing Group of Organism. In Press.

the public eating place as the chief focus of distribution it was determined to make a laboratory investigation of eating utensil sanitation in public eating places. These investigations included a study of the bacterial counts of hand and machine washing dish water, and of spoons just before and after washing by the hand and by the machine washing methods. In Table I there is presented a consolidation of these investigations which were carried out during the winter and early summer of 1919 at the Port of Embarkation, Newport News, Va. The technic of collecting and examining the specimens was as follows: The dish water specimens were collected from the restaurants in 200 cc. quantities in sterile containers. In order to determine the efficiency of washing eating utensils, it was necessary to make bacteriological examinations of these before and after they were washed. Since the spoon actually enters the mouth of the one who uses it, this utensil was chosen as the subject of our investigations. At each visit to the public eating place, unwashed but used spoons as well as washed spoons were collected in lots of twenty-five each. Each lot was placed in a separate wide mouth bottle containing 200 cc. of sterile water of a temperature of approximately 45° C. and shaken for three minutes. By using this amount of water the ladles of the spoons only were submerged so that there was no contamination of the wash water from the handle of the spoons.

As shown in the tabulation, these investigations were carried out on specimens from eating places where the hand method was used and from those where the dishes were machine-washed. Three of the restaurants installed machines while the work was in progress, so an excellent opportunity was afforded for comparison. It will be noted that 134 specimens of dish water and that 2,610 spoons, or 125 different lots of spoons, were subjected to bacteriologic examination.

While the average bacterial count of hand washing dish water was 6,792,500 per cc., it will be noted that the count of machine washing water was but 960 per cc., a reduction by the use of the latter method of 99.98 per cent. This marked reduction shows the advantage of mechanical washing, by which method the water is used at or near the boiling point. Is there a reduction in the bacterial count of machine-washed eating utensils over that of hand-washed, corresponding to this reduction in the wash water counts for these two methods of washing? The average bacterial count per spoon for those unwashed, was 674,500, while that for spoons which had been washed by hand was 154,000 per spoon. By this method of dish washing, then, but 78.82 per cent of the organisms were removed. In contrast to this will be noted that for machine-washed spoons the average count was but 4,790 organisms per spoon, or a reduction of 99.17 per cent. This reduction corresponds to that of the dish water counts for the two methods of washing. In other words, a determination of the bacterial count of dish water from public eating places gives a fair indication of the efficiency of eating utensil sanitation.

These favorable sanitary results secured by the use of the mechanical washer over that of hand washing are accounted for by the use of boiling water by the former method. When dishes are hand washed, they are not rendered aseptic, for the water is of such a temperature as can be readily withstood by the hands. The average temperature of 72 specimens of hand washing dish water was but 44.5° C. In contrast to this low temperature, which has no sterilizing effect on bacteria, it is to be pointed out that of fifty-

TABLE I.—Comparison of Bacterial Counts of Hand and Machine Dish Washing Methods

**Average count 22 specimens.

five specimens of machine washing water, the temperature was 91° C. When dishes are hand washed, they should first be treated with a liberal amount of boiling water. This water should not be robbed of its sterilizing action by the immediate addition of cold water, but full advantage of this action should be taken by allowing the water to cool of its own accord to such a temperature as the hand can stand.

The Practical Application

The interesting points in connection with the results of these investigations are as follows (1) From the esthetic standpoint the almost universal practice of reducing the number of organisms on eating utensils by only four-fifths is to be condemned. This partial reduction is definite information that the utensils are not clean. (2) Of practical importance is the fact that, since eating utensils enter the mouth where they become contaminated with organisms from that cavity, it is evident that if only four-fifths of these are removed by the washing process there must be a considerable exchange of mouth organisms among individuals through hand-washed eating utensils. (3) The use of boiling water during the process of cleaning eating utensils, whether cleaned by hand or machine, renders them sterile in so far as the acute saliva infections are concerned.

There is abundant proof that eating utensils are the major avenue of transmission of the saliva-borne infections. In former reports it was pointed out that of eating utensils used by cases or healthy carriers of the hemolytic Streptococcus, 87 per cent were still contaminated with this organism after they had been hand washed. Also, that 25 per cent of the animals inoculated with rinse water specimens of hand-washed eating utensils used by open tuberculous patients, died from tuberculosis, and that eating utensil asepsis or pasteurization in the Army, in public institutions, and among civilians, gives a protection of 80 per cent against the acute virus infections.

As indicated in the tabulation here presented, we now know that of the total organisms on eating utensils, 21.8 per cent remain adherent thereto after the utensils are used and hand washed. This would seem to indicate the reason for the high carrier rate, the high sick rate, and the high mortality rate of the saliva-borne infections—in brief, the high transmission rate—and to explain the futility of the attempt to control this group of diseases on the theory that they are wholly air-borne. We also know that there are many permanent carriers of tuberculosis and of the pneumonia producing organisms, and that during the epidemic period of the acute virus infections—as influenza—temporary carriers, and perhaps also chronic carriers, make up a comparatively large percentage of the population. We are all familiar with the healthy carrier of diphtheria and the mild unrecognized cases and carriers of poliomyelitis and meningitis. With these two factors, the insanitary eating utensils, and the high carrier rates of the saliva-borne infections, in mind, it is apparent that there is a high rate of exchange of infectious organisms between individuals through eating utensils.

In the control of this group of infections the public eating place must be eliminated as the central focus of distribution. This can be accomplished by eating utensil pasteurization. Managers of the more progressive public eating places take advantage of economy in the use of the mechanical dishwasher with its boiling water. The public health officer will realize that the use of the machine has an advantage in addition to economy; *viz.*, there is no public health measure today equal in importance to the pasteurization of eating utensils in public eating places. The value of pasteurization of eating utensils in the home by the use of boiling water should become common knowledge. This procedure should become a universal practice, both in the public eating places and the home. Its universal application as a control measure in the saliva-borne infections will accomplish more than will all the other measures combined.

Just as there is a reduction in the bacterial count of polluted public water supplies by filtration and chemical treatment, so also there must be a reduction in the bacterial contamination of eating utensils by the use of boiling water.

Conclusions

(1) First and foremost in the control of the saliva-borne infections is a reduction in the transmission rate. This will diminish the large mass of carriers, who are far more important as sources of distribution for this group of infections than the actual cases in the hospital.

(2) Further attempts should be made to determine with accuracy the major and minor routes of transmission and the several links in the chain of these routes.

(3) From our studies it appears that eating utensils rank foremost as transmitting agents of the saliva-borne infections. These utensils either enter the mouth or touch the lips; they become contaminated with organisms of the oral cavity; they are still contaminated after they are hand washed, and the next user acquires this contamination.

(4) The use of utensils contaminated with or-

ganisms of one or more of the saliva-borne diseases does not necessarily mean infection, but this major avenue of transmission is so prolific and so universal that a large number of saliva-borne infections occur and cause more deaths than all other groups combined.

(5) There is no avenue of indirect transmission more frequent than through insanitary eating utensils. We eat three times a day with utensils previously used by others; these utensils are not rendered aseptic; they actually enter the mouth—the normal portal of entry of the saliva-borne infections, and preventive measures must take them into account.

(6) Our greatest hope for the control of this group of infections, especially tuberculosis and the fatal secondary pneumonias, lies in the universal practice of eating-utensil pasteurization by the use of boiling water. This applies alike to the home and the public eating place. In the home, eating utensils should be scalded before they are washed; in the public eating places they should be scalded in the process of mechanical washing. In public eating places this procedure of cleansing is not only economical, but its value as a public health measure in eliminating the primary center of saliva-borne disease distribution should be recognized.

ARE WE CONTROLLING VENEREAL DISEASE?

By JULES SCHEVITZ, General Secretary, Oklahoma Tuberculosis Association, Oklahoma City, Okla.

OF ALL the products of American enterprise and ingenuity brought out by the last four epoch making years, none has challenged the interest of the thinking world more decisively than the American plan of venereal disease control. It is the answer of a young, idealistic, essentially clean thinking nation to a problem that has baffled civilization for centuries. It is America's contribution to a public health question of international scope and when, in addition to being an ideally comprehensive program, it proves itself to be a thoroughly practical one, it commands respect.[1]

Plan a Fourfold Program

The above passage expresses in no uncertain terms the attitude of health workers in this country toward the "American Plan" for venereal disease control. We are very proud and enthusiastic, and rightfully so, of the high standards and ideals upon which our program is based. We are ready to admit that we have selected the best features of the various continental plans and have combined them in one single program which we believe to be the most effective yet designed.

The fourfold program under the American plan includes law enforcement, medical, educational, and recreational measures. The suppression of prostitution is the goal of the law enforcement efforts; proper and adequate medical facilities for the treatment of venereally infected individuals is the aim of the medical program; education of the people with regard to the nature, modes of transmission, prevention, and treatment of venereal disease, and the fact that sexual continence is entirely compatible with good health are the functions of education; and provision of wholesome recreational facilities for a healthful outlet of the natural energies constitutes the fourth phase of the plan.

The program recommended by the United States Public Health Service to bureaus of venereal disease in state health departments includes the following:[2]

(1) Securing the reporting of venereal infections in accordance with State laws or State boards of health regulations.

(2) Carrying on repressive measures, including the isolation and treatment in detention hospitals of infected persons who are unable or unwilling to take the necessary measures to prevent themselves from becoming a menace to others.

(3) Establishment of free clinics for the treatment of venereal diseases, and extending the facilities for early diagnosis and treatment by providing proper laboratories to make exact diagnosis and examination to determine when patients might be released as non-infectious.

(4) To carry on a general educational campaign to inform the public as well as infected individuals regarding the nature of these diseases and the manner in which they are spread.

The suggested budget as recommended to state divisions of venereal disease allows 50 per cent for treatment, 20 per cent for repression, 20 per cent for education, and 10 per cent for administration.[3] With the exception of two states and the District of Columbia, the Public Health Service has received cooperation from every state as required under the Chamberlain-Kahn Act, and several million dollars have been spent for the conduct of this program.

There can be no doubt as to the value and beneficial results derived from our present campaign.

2. Pierce, C. C.: Public Health Service Program for Nation-wide Control of Venereal Diseases, Public Health Reports, May, 1919, p. 1056.

3. Typical Budget for Effective Anti-Venereal Disease Activities, Public Health Reports, 1919, p. 504.

Records show[4] that from July 1, 1918, to September 30, 1919, 171,391 cases of gonorrhea and 128,751 cases of syphilis were reported throughout the United States. Many million pieces of literature were distributed by the Public Health Service and the American Social Hygiene Association. More than four hundred clinics have been established where venereally infected patients may receive treatment.

Merits of Present Methods

When we come to ask the question as to what effect our campaign has had upon actual prevention of venereal disease, we find ourselves at a loss to give a definite response. The control of venereal diseases is very similar to that of other communicable diseases, and is based upon prevention of infection, reduction in morbidity, and reduction in mortality. If we fail in the first instance we attempt the second, and, failing there, we must direct our efforts toward the third. In the control of tuberculosis very little can be accomplished toward the prevention of infection, though a great deal can be done in reducing morbidity after infection. Unfortunately, this is not the case with the common venereal diseases, because of the brief period elapsing between infection and active disease.

According to available statistics, the fatality of the venereal diseases is not very high. In other words, the reduction of mortality is not the most pressing need. Since very little can be accomplished towards reducing morbidity, it is evident the great saving lies in the prevention of infection. An examination of the expenditures in our venereal disease campaign indicates that a large proportion of our funds is devoted to treatment. While the value of prompt and adequate treatment cannot be discounted, it is reasonable to expect that an increasing proportion of the funds be devoted toward attaining the goal of preventing infection.

A considerable share of the funds is used for purposes of education, which must of necessity be directed mainly at prevention; yet there seems to be some question in the minds of certain workers whether the present form of education is all that is needed. This is particularly true in England, where there is a distinct division of opinion as to the merits of our present methods.

We all admit the disastrous effects of venereal diseases; we are all familiar with numerous instances of innocent infection and misery resulting from it. The charge has been made[5] that by omitting from our campaign instruction in prophylactic measures "we are actually guilty of encouraging the spread of venereal diseases." In all the vast amount of material prepared in this country on the subject of venereal disease control, the question of prophylactic instruction is conspicuous by its rarity. In the few instances where the subject is broached it is veiled under a discussion of "early treatment." The United States Public Health Service, in referring to the "early treatment" in the venereal disease program states[6]: "It is not designed to establish prophylactic or early treatment stations primarily as such, but all clinics should be prepared to intelligently administer this treatment to voluntary applicants who give a history of exposure within a few hours immediately preceding their application."

The controversy which has been going on in England for the past several months regarding the place of venereal prophylaxis brings out many points which probably apply equally well to the program in the United States. During the war the National Council for Combating Venereal Diseases conducted a program similar in most respects to that carried on in this country. Emphasis in the educational campaign was placed on teaching the dangers of venereal infection and the value of continence. A number of army medical officers who claimed that this campaign had but little appreciable effect on the prevalence of venereal diseases instituted a system of personal prophylaxis with excellent results. As recounted by one officer,[7] "I gave careful instructions and repeated them daily to all men joining the station. . . . Immediately venereal diseases vanished from our units. For five months I did not see a freshly contracted case. In two years and four months only seven cases originated among my men." This experience is by no means confined to this particular instance. The following table[5] indicates similar results in the United States Navy where prophylactic measures were employed:

Number of Treatments, Failures, and Percentages for Each Hour After Exposure

Hours Subsequent to Exposure	Number of Treatments	Number of Infections	Per Cent of Infections
1	1,180	1	0.08
2	1,172	7	0.59
3	521	1	0.77
4	330	2	0.61
5	199	3	1.57
6	321	5	1.58
7	277	6	2.27
8	390	16	4.22
9	283	10	3.62
10	214	11	5.14
More than 10	216	16	7.40
Total	5,103	81	1.58

6. Place of Early Treatment in Program of Venereal Disease Control, Public Health Reports, April, 1919, p. 789.

7. Reid, Sir Archdall, M. B., C. M., F. R. S.: Prevention of Venereal Disease, Public Health, London, 1919, xxxiii, No. 1, p. 5.

8. Circular Letter of Society for Prevention of Venereal Disease, Wansey Bayley, Honorable Secretary, 143 Harley Street, London, W. I.

Of the 1,180 treatments given during the first hour after exposure there was but one infection. According to Dr. Riggs, there was considerable doubt as to whether this case was genuine or not.

Applied to Civilian Control

The English army medical officers referred to above, upon return to civilian life, desired to bring into practice among the civilian population the methods found so effectual in the army. The opponents of this plan promptly charged that the widespread knowledge of methods of self-disinfection would result in increased immorality by making illicit relations safe, and it was also claimed that disinfection would not always prove effective. The latter objection can be promptly overruled by the experience of numerous medical officers both here and abroad. The contention that spreading information concerning self-disinfection leads to increased laxity in morals is probably of little weight. "Unless it can be demonstrated that the fear of venereal disease tends on the balance to keep men moral, any attempt to obstruct the application of suitable sanitary measures to these disorders is merely an act of vengeance," according to Sir Archdall Reid in an article on the "Prevention of Venereal Disease."[7] It is a question whether men who understand most about these diseases are the most moral.

Ablution rooms were maintained throughout the army, but this measure was found less effective than furnishing the men with the disinfectants or advising them where they might be obtained.

This discussion became even more intense since the publication of the Report of the Interdepartmental Committee which sustained the measures recommended by the National Council for Combating Venereal Diseases. The advocates of personal prophylaxis include the leading medical officers of health in England as well as numerous physicians throughout the country, and these workers have become even more stirred to action since the publication of the unfavorable report. In order to crystallize the movement for prophylactic instruction there has been organized another national organization known as the Society for the Prevention of Venereal Disease, whose aims and objects are stated as follows:[8] (1) To instruct the public to (a) the vital importance of self-disinfection at the time of exposure to risk as a preventive of venereal disease, and (b) the methods of application. (2) To advocate such further steps for the prevention of venereal disease as may be deemed advisable.

Those persons desiring to take out membership in this organization are obliged to sign the following declaration: "I hereby declare that in my opinion it is essential for the reduction and final elimination of venereal disease, that the public should be instructed in the principles and practice of immediate self-disinfection; and I further accept and endorse the aims and objects of the Society."

Prevention a Social Gain

Sir John J. W. MacAlister, secretary to the Royal Society of Medicine, speaks of the moral issue injected into this controversy as follows:[9] "There is glib but unthinking talk of the so-called moral question; but to me the highest morality should regard it as the worst crime against God and man to allow the innocent to suffer for the guilty. If in combating this scourge it is even necessary to make sin easier and safer for the sinner, that is a matter between the sinner and his God, but it is our duty to leave no stone unturned to insure that the sinner shall not in his sin bring untold suffering, disease, and death upon the innocent."

The outcome of this discussion in England will naturally have very marked effect in this country, and it might be a desirable thing to bring about a similar discussion here. In an outline of the activities for reducing the prevalence of venereal disease in the United States Army it is stated that[10] "The provision of prophylactics in regimental infirmaries . . . is imperative in any sane attack upon venereal diseases." Exner in his studies on prostitution and its relation to the army on the Mexican border states[11] "the venereal prophylactic measures carried out in the Army have in large degree proved effective in preventing venereal diseases." and, further, "whichever way our sympathy may lie in the discussion of the desirability of 'making prostitution safe,' by employing prophylactic measures, we must recognize that this has been a gain not only in army efficiency, but apparently a great social gain."

If there be any real merit in the use of prophylactic measures in the civilian population, as is urged by the leading health authorities in England, certainly the importance of preventing infection is of sufficient weight to warrant its most earnest consideration.

DAMAGES FOR LEAD POISONING

Under a recent decision of the Supreme Court of Illinois it was held that an employee may recover damages for illness caused by lead poisoning resulting from employer's failure to safeguard employees against lead poisoning. This case may be found cited in *Labanoski vs. Hoyt Metal Company*, 126 N. E. 548.

TUBERCULOSIS IN CLEVELAND—A SURVEY OF IMMEDIATE NEEDS

By D. B. ARMSTRONG, M.D., Special Investigator, Cleveland Hospital and Health Survey, Framingham, Mass.

CLEVELAND has the fortunate habit of frequently taking account of stock. It is a community which believes in frequent appraisal, and seems to be desirous of facing its problems with courage and constructive vision. A recent manifestation of this spirit is the general health and hospital survey carried out under the direction of the Cleveland Hospital Council, a group in the Cleveland Federation of Social Agencies. This health and hospital survey, under the supervision of a special committee headed by Mr. Malcolm F. McBride of Cleveland, has endeavored to cover many of the vital health factors of Cleveland, including hospital facilities, dispensary service, infant welfare work, public health nursing, school hygiene, industrial medical work, social hygiene, mental hygiene, and tuberculosis. The work is under the general direction of Dr. Haven Emerson of New York City, ably assisted by Dr. Gertrude E. Sturges of Ohio.

Cleveland has always been a pioneer community, a community with courage, resourcefulness, and vision. A forward looking city guided by the spirit of cooperation and good will, it has made a true appraisal of its genuine needs.

Having accomplished much in the past, it was legitimate to ask: "What is the next step in the control of tuberculosis in Cleveland?"

The willingness of Cleveland to face its problems with patience and courage, its social motive, its spirit of idealism—all give assurance of exceptional achievement in the future.

It remains for an American municipality to demonstrate that tuberculosis can, under intense urban conditions, be controlled.

The Next Step in Cleveland

It is the object of this paper to summarize briefly the results of one particular aspect of this survey, namely, the analysis of tuberculosis conditions in Cleveland. A full report will shortly be published with other material from the Cleveland survey, and can be secured through the Cleveland Hospital Council. It is possible here to give in the most summary fashion only the methods and objects of this survey, together with the principal findings. Possibly a brief indication of the methods of approach may be of some suggestive significance in the development of similar programs in other communities.

The carrying out of this special study in Cleveland has been a most agreeable task for numerous reasons. In the tuberculosis field, Cleveland has been in many respects a pioneer community. Having accomplished much in the past, it was legitimate for the community now to ask: "What is the next step in tuberculosis work in Cleveland?"

In the past, Cleveland, through its health and tuberculosis agencies, has admirably accepted the challenge to make Cleveland the national leader in tuberculosis work. The community has met its obligations in a notably conspicuous way. Its past experience, coupled with a willingness to face its current and future problems with patience and courage, gives assurance of exceptional accomplishments in the future.

In discussing the prospects of future developments in the Cleveland tuberculosis program with the health and civic leaders in the community one is impressed favorably with the attitude quite generally maintained toward pressing local problems. The leaders seem to recognize current limitations in health and tuberculosis work. There is manifested an excellent spirit of cooperation and good will between local agencies. The heads of local movements are forward looking and sympathetic to fresh suggestions.

The primary objects of the tuberculosis survey in Cleveland were as follows: (1) An analysis of "past history" as to tuberculosis, a study of its past incidence as to mortality and morbidity, and an analysis of previous experience as to methods of control. (2) A study of the present problem, its magnitude and its relative significance as a disease factor in the life of the municipality. (3) An analysis of existing measures and equipment for meeting the problem. (4) A determination of the chief immediate needs and outstanding inadequacies in the present machinery for tuberculosis control. (5) An approximation of the more obvious and urgent recommendations growing out of such an appraisal. In endeavoring to accomplish these ends a specific program of inquiry was outlined as a basis for approach to the Cleveland situation. An effort was made to accumulate knowledge with reference to past and present tuberculosis factors in Cleveland, under the following general headings:

I.—Statistics.

(a) Population: General knowledge regarding age and sex distribution, nativity, etc.

(b) General Mortality: General mortality rates for at least the past decade; for residents and non-residents; for leading causes, etc.

(c) Tuberculosis Mortality: (1) Primary to an analysis of tuberculosis mortality is the question of the reliability of death certification; and (2) tuberculosis mortality for a few years back, according to residence, age, sex, forms of tuberculosis, occupation, nativity, community sections, etc.

(d) Tuberculosis Reporting: The amount of tuberculosis reported; the ratio of known, active, and arrested cases to deaths; and an analysis of reported cases according to sections, etc., with ratios of reported cases to deaths by sections. Under this heading should also be considered the methods of case classification.

II.—Legislation.

The extent of legislative backing and the efficacy of legislative enforcement as regards tuberculosis reporting, segregation, clinic and hospital provision, routine medical work in schools and factories, and nursing facilities are included, as well as general sanitary considerations, such as milk control, respiratory hygiene, general cleanliness, housing, and, finally appropriations.

III.—General Sanitation.

Fundamental to an analysis of a tuberculosis situation is at least a general knowledge of sanitary conditions as reflected in general cleanliness, street conditions, housing, milk and food control, the suppression of common utensils, the prevention of spitting, the promotion of personal hygiene, and the medical control of open cases by segregation.

Disease detection should comprise an analysis of facilities and methods for the detection of tuberculosis, including a study of clinics, and of nursing methods. The efficacy of existing general medical machinery for age groups, work among infants, pre-school and school children, and factory workers. The percentage of reported cases in an early or advanced stage was noted as a reflection of the efficiency of disease detecting devices as well as the possible utilization of general medical examination campaign methods or of special consultation services.

V.—Treatment.

Under treatment, in particular, the problem was approached from the quantitative as well as the qualitative point of view. The nursing problem, for instance, was studied from the point of view of the relative utility of generalized compared with specialized nursing methods.

A study was made of specific treatment measures, including home treatment, as to nursing facilities and matters of equipment; clinics and dispensaries; tuberculosis classes; institutional methods, such as camps, open air schools, sanatoriums, hospitals, and preventoriums; relief measures; domestic science and home hygiene instruction; general social and occupation adjustment.

VI.—Subsequent Observation.

Investigation was made into the methods of control of the returned or arrested case, his relief, his working adjustment, his hygienic education, and his medical supervision.

VII.—Prevention—Education.

The effectiveness of the preventive program was measured by the early detection of disease, the control of milk supplies, the segregation of open cases, and general sanitary precautions. Note was made of the use of special educational procedures such as disease suppressive as well as health creative personal hygiene propaganda, home hygiene education, domestic science work, the development of nutrition classes, summer camps for the subnormal children, and preventoriums.

VIII.—Research and Teaching.

Under this heading the utilization of opportunities for laboratory and social research was included, together with the methods of institutional instruction for lay and professional groups.

IX.—General Organization.

Analysis was made of organized work for the detection, control, and prevention of tuberculosis.

(a) Public machinery, its efficacy, the adequacy of appropriations, records, filing system, etc.

(b) Private organization machinery—its business like character, full or part time services, its use of lay and professional backing, its usefulness for preventive education, for the initiation of new services, for the coordination of public and private established services, and for the observation of public services.

Cooperation in Health Survey

On the basis of this program a careful statistical and field study was carried out, aided very materially by the other investigators cooperating in the general Cleveland Health Survey. Particular light was thrown upon the tuberculosis situation by the investigators in the nursing, industrial, and child hygiene fields.

In carrying out the direct phases of the tuberculosis survey special activities were greatly facilitated by the direct cooperation and aid furnished through the local health agencies, particularly the City Department of Health, the Tuberculosis League, the Visiting Nurse Association, the Associated Charities, and similar agencies.

The report in full, when eventually published, will probably be presented from the points of view indicated by the preliminary chapter headings, such as: "Objects and Methods of the Survey," "Special Provisions for Fighting Tuberculosis in Cleveland," "General Measures for the Prevention and Control of Tuberculosis in Cleveland," "Statistical Findings," "General Summary of Activities and Equipment," and "Conclusions and Recommendations."

The outstanding facts in the tuberculosis survey were presented at a recent meeting in the Chamber of Commerce Building at Cleveland, at the annual meeting of the Cleveland Tuberculosis League, before an audience of physicians, nurses, city officials, members of the League, and others. At the time of this meeting a preliminary synopsis of the findings of the survey was prepared for distribution. This summary presented the survey facts as follows:

Equipment for Fighting Tuberculosis

Tuberculosis is in large measure a preventable and curable disease, yet each year between ten and twelve hundred Cleveland citizens die from this cause alone. Nearly six thousand known cases are constantly afflicted with this disease—a social handicap and economic burden to themselves, their families, and the city.

Cleveland has been, in comparison with other American cities, by no means backward in the development of machinery for defense against this "captain of the men of death." Public and private interests have provided: (1) A Bureau of Tuberculosis in the Department of Health—at present without a head. (2) Seven Department of Health tuberculosis clinics in the health centers distributed throughout the city. (3) A staff of eighty or more general public health nurses in the Department of Health, devoting considerable time to finding and treating tuberculous cases. (4) Municipal or private institutions, providing approximately five hundred beds for the care of early and advanced, childhood and adult, pulmonary and non-pulmonary cases of tuberculosis. (5) A Tuberculosis League, responsible for the initiation of many of the excellent anti-tuberculosis provisions in the past, and alive to its present obligations for educational and other activities aimed at the control of this disease. (6) A background of legislative provisions, a system of general sanitary and milk control, organization for infant welfare and school health work, and for relief dispensation,—all important in the war on consumption, and all comparing favorably in theory and practice with the average American city.

Past Accomplishments

With this machinery for tuberculosis control, Cleveland's accomplishments are of no mean order. Their appraisal is of great significance, for if we are to estimate the potential possibilities of a community we must know its "past performances." From this point of view the outlook is immensely encouraging. Among the mileposts of progress in Cleveland's fight on the Great White Plague are:

(1) A courageous pioneer development of a health center system, coupled with generalized nursing which constitutes an experiment and demonstration in social machinery for disease control of immense national value.

(2) A gradual development of tuberculosis clinical attendance of thousands annually, totaling over sixty-one thousand for the period 1914-18.

(3) The registration of 4.7 active tuberculosis cases in 1918 for every annual death, a ratio that compares favorably with the usual American registration of three or four cases to a death.

(4) The establishment of the Warrensville Sanatorium, most noteworthy among Cleveland's institutional provisions for tuberculosis, in many respects a model institution both in equipment and management.

(5) An encouraging reduction, along with most other communities, of the annual tuberculosis death rate, falling from 225 per hundred thousand living, the rate in the period from 1865 to 1869, to 145 per hundred thousand from 1913 to 1917.

Immediate Needs

In spite of these accomplishments much remains to be done if the disease is to be reduced to a minimum—measures that do not await fresh discoveries in disease control, but which depend on the use of known and demonstrated means for tuberculosis elimination. If we measure Cleveland against ideal standards, it is because of our faith in the city's ability to approximate these standards:

(A) Tuberculosis is a communicable, widespread infection, an infection that can be reduced by:

(1) Education in personal hygiene. Very little is being done in this direction at present in Cleveland, either to suppress disease transmission, as through the elimination of common utensils, or to increase general resistance, as through the promotion of more adequate milk consumption by children.

(2) Control of dangerous infectious cases. Cleveland has the legislation necessary for the segregation of such cases, but employs it rarely.

(3) The prevention of dangerous spitting. In 1918 there were no convictions for violation of the anti-spitting ordinance.

(4) The sanitation of milk supplies. Cleveland has a fair milk supply, pasteurization insuring against bovine tuberculous infection. Every effort should be made to uphold and enforce the present milk standards.

(5) Adequate housing conditions. Cleveland faces a serious housing problem, insistently demanding radical treatment if tuberculosis and other diseases are to be controlled.

(B) Tuberculosis is a preventable disease, to be reduced in its active and advanced forms by:

(1) The reduction of economic strain by the elimination as far as may be possible of excessive fatigue, long working hours, and time lost through inadequate transportation facilities; by the provision of opportunities for healthful recreation for working people; by the development of facilities for purchase of food and clothing at minimum cost through company or cooperative stores; by the training of girls in domestic economy and the art of buying and cooking food; and by the development of adequate industrial health services. Employers and employees must come to realize that their common interest in the health of industrial personnel can best be served through the institution of physical examinations under conditions mutually satisfactory.

There has been in Cleveland notable progress in the field of industrial hygiene, yet the amount of tuberculosis which has been found through the examination of employees or applicants for employment in the industries of Cleveland is negligible. It has been overlooked either because examinations have been made too casually or because they have been made by physicians very ill equipped to examine for pulmonary disease.

(2) The detection of early cases. At present 50 per cent of the cases discovered are advanced. This should be reduced to 25 per cent, at least, through the training of clinic and general physicians in the detection of early signs of disease, and through the help of expert advisory consultation services on diagnosis in difficult or doubtful cases. At present Cleveland is registering about four and one-half cases for every annual death, while the probable ratio of active cases to deaths, if all were discovered, is nine to one rather than four and one-half to one.

(3) More adequate provision for institutional treatment. At present 44 per cent of the male patients at Warrensville leave "unimproved." The potential effectiveness of the city's equipment is in great measure wasted unless this percentage is materially reduced through social and educational devices and more effective "follow-up."

(4) Prompt reporting upon diagnosis. At present from 20 to 30 per cent of the cases are not reported until death.

The Recommendations Made

To meet these deficiencies in the Cleveland tuberculosis program, symptomatic as indeed they are of conditions generally elsewhere, certain specific suggestions are presented. If ways can be found for their adoption, it is confidently believed that Cleveland will soon deserve and receive the Nation's universal acclamation as the city that fought tuberculosis to a finish.

(A) Find more cases of early tuberculosis. If tuberculosis is to be combated successfully, cases must be found early. In Cleveland, as elsewhere, the "next step" in tuberculosis is the *first step*, namely to find the early, undiscovered cases.

(1) By educational methods and, where violation is persistent, by legal measures, stimulate compliance with city ordinance requiring the reporting of tuberculosis as soon as diagnosis is established.

(2) By the establishment of an expert medical advisory consultation service on diagnosis and treatment, to operate through the health centers under the auspices of the Department of Health or the Tuberculosis League.

(3) By providing post-graduate medical training, through the medical school or otherwise, for the training of clinic physicians and general practitioners in the detection of incipient signs and symptoms in tuberculosis.

(B) More adequate treatment.

(1) By the provision of 450 additional beds for institutional cases, for advanced and early types, for adults and children, at the City Hospital and Warrensville.

(2) By improved methods of sanatorium and hospital treatment encouraging the patients to persist in the treatment until arrested or cured, and following them up to insure proper social and economic adjustments to work and to life.

(3) By providing a more adequate number of nurses to find suspicious cases and persuade them to come to doctors for diagnosis, 150 more nurses being needed on the staff of Department of Health.

(C) Prevent more infection.

(1) By an intensive educational campaign, through the Tuberculosis League, on the dangers of infection, personal hygiene, food hygiene, and measures to increase resistance.

(2) By improved sanitary practices, involving the suppression of spitting, the segregation of dangerous consumptives, an improvement in methods and equip-

ment for living, including adequate housing to prevent inevitable infection through congestion.

(D) More complete organization.

(1) A full time chief in the Bureau of Tuberculosis, to aid and cooperate with other agencies in the further development of the health centers, the institutional program, the post-graduate training, the consulatation service, and the educational activities.

(2) The adequate financing and staffing of the Tuberculosis League for educational and possibly medical consulting work, involving an estimated annual budget of from twenty to thirty-five thousand dollars, depending upon the service undertaken.

(3) A full fledged medical, nutritional, and educational program in the schools and factories of Cleveland.

Cleveland has always been a pioneer community, a community with courage, resourcefulness, and vision. A forward looking city, guided by the spirit of cooperation and good will, it is seeking a true appraisal of its genuine needs. In the past the city has admirably accepted the challenge to make Cleveland the national leader in health and tuberculosis work. Its obligations have been met in the Cleveland way.

Having accomplished much, it was legitimate to ask: "What is the next step in the control of tuberculosis in Cleveland?"

The willingness of Cleveland to face its problems with patience and courage, its social motive, its spirit of digested idealism, all give assurance of exceptional accomplishment in the future.

It remains for a leading American municipality to demonstrate that tuberculosis can, under intense urban conditions, be controlled. Cleveland possesses the knowledge, the resources, and the spacious minded leadership essential to this task.

VOCATIONAL SCHOOL FOR THE TUBERCULOUS, CHICAGO, ILL.

THERE is nothing new about the theory of special training for the handicapped, or even the therapeutic effects of work properly adapted to the needs of the chronic. It has long been recognized that the mental effect of idleness upon those by disease condemned to a life of uselessness is so depressing as to hasten their death. For years there has been a discussion as to the sorts of activity that could with safety be introduced into tuberculosis sanatoriums. The old treatment prescribing complete rest and fattening foods has not solved the problem of tuberculosis. That it cannot be assumed that every gain in weight means a corresponding gain in resistance to disease is proved positively by the reactivation of tuberculosis in sanatorium patients discharged as cured, and by the fact that they also show a lack of resistance to other contagions.

Herman Brehmer introduced graduated exercises in his treatment of tuberculosis some sixty years ago. Dr. Patterson, of Frimley, England, found that exercise stimulates the production of antibodies and that the induced deep breathing gives tone to muscle and blood vessels. Dr. Edward McSweeney of the New York State Department of Health went a step further and introduced in the treatment of his patients properly selected work from fifty occupations. Most of the sanatoriums of the country have departed from the program of absolute rest.

The advantages of the work régime have been notably demonstrated by the Chicago Municipal Sanitarium. The vocational school for the tuberculous, conducted at this institution, is the subject of a report by Dr. John D. Robertson in the *Bulletin* for January, 1920. Graduated labor was introduced in their treatment in 1917, when twenty-five patients under close supervision were given the care of their cottages. It was soon evident that the feeling of cheer their useful activity induced materially aided in their cure. To carefully supervised useful work was soon added the idea of utilizing the period of enforced rest for vocational training, by which means the patient may return to the industrial world better equipped than when he left it, or may be prepared to earn a livelihood in a new occupation not hazardous to his health. The training has become increasingly popular with the pa-

The horticultural class receiving instruction in evergreen tree culture.

The manufacture of the sanatorium drug supply affords training in pharmacy.

tients and has furnished an added incentive to them to get well.

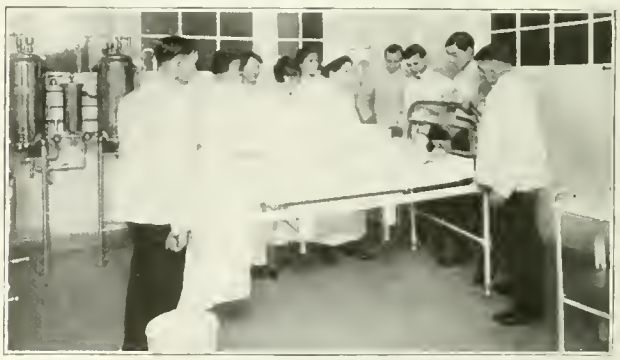
Each prospective student is advised as to what course he can most advantageously take up. A course in English is recommended to every patient, especially to the foreign-born patients. It really seems a waste of opportunity to allow any foreign-born person to be present in any institution belonging to the city or Government without teaching them something of the English language, and it seems as if it would be desirable to require every such patient who has passed the febrile condition of disease to spend at least an hour daily in the study of the English language supplemented by the study of civics.

The class work in manual training includes designing, cabinet making and repairing.

Dietetics and cookery are taught both by lectures and demonstrations.

The school even provides for the man of exceptional ability. To him is offered the choice of studying pharmacy, x-ray work, or photography, electricity, or routine laboratory work. A course covering six months of study, lectures, demonstrations, and active experience provides an undergraduate nurse course, its object being not only to prepare for professional nursing but to inculcate the principles of cleanliness and first-aid in the home and community. A course in domestic training covers all of the essentials of hospital and home food preparation for both the sick and the well. The Department of Agriculture and Horticulture prepares for a decidely healthful employment. Practical demonstrations are given and they are directed in the use of current garden and farm papers regarding various phases of the work. There are courses in telegraphy, woodworking, and shoe repairing.

The class in poultry raising takes care of more than two thousand chickens for the sanatorium.



Lectures and practical work provide a thorough and useful course in general nursing.

Two courses have contributed greatly to the morale of the patients—the course in barbering and the one in beauty culture. Any patient desiring this service receives it at the school free, and attendants say that there is nothing that will so put heart into a bedfast patient as this service carried into the wards by advanced students.

Recreation is also provided for, and the Hall for Health Education provides many lectures on ethical subjects, with music and private theatricals.

Those too young to take up the study of a trade receive the regular school subjects, toy making, and rug making. It is planned to carry these subjects into the wards for the benefit of the bedfast patients. The object of the school is therapeutic, but the economic gain adds rather than detracts from its curative purpose.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M OLMSTED, R. N., *Editor*

MISS NOYES HONORED

AT a recent meeting of the three national nursing organizations held in April in Atlanta, Ga., Miss Clara D. Noyes was re-elected president of the American Nurses' Association. Miss Noyes was for three years president of the National League for Nursing Education, and now enters her third year as president of the American Nurses' Association.

All nurses feel that this is just as it should be, as Miss Noyes has proved herself a leader among the executives in the nursing profession, and by reason of her keen mind and her exceptionally capable, impressive personality she has won the confidence and support of the American nurses throughout the entire country.

Miss Noyes has had long and varied experience in executive positions. A graduate of Johns Hopkins, she has been superintendent of St. Luke's, New Bedford, and Bellevue, New York. After the death of Miss Jane Delano she was appointed director of the department of nursing of the American Red Cross.

Miss Noyes was recently decorated with the Patriotic Service Medal of the American Social Science Association and of the Council of National Institute of Social Science.

We are sure the nurses of this country are strongly backing Miss Noyes in all the efforts she is so steadily promoting for the advancement of the nursing profession at a time fraught with many difficulties and perplexities.

Miss Clara D. Noyes (re-elected), President of the American Nurses Association.

THE SHORTAGE OF NURSES

THERE are so much discussion at the present time of the question of the shortage of nurses and so much criticism of nursing education in general that a few facts may be of interest to the readers of MODERN MEDICINE.

It is true the demand for nurses far exceeds the supply. The public has twice recently suffered real tragedy in epidemics because of lack of nurses. The advance in the prevention of disease, and of public health work in schools, factories, cities, and on the prairies is being hampered and threatened by a shortage of those workers who carry to the people the message of right living and good health.

There is no need to state here that the woman with a nurse's training, skilled in the relief of suffering and the bedside care of the sick, is the messenger best able to reach the individual ear and make effective a teaching too easily ignored. As Florence Nightingale once said, "The word that sticks is the word that follows work."

Everywhere the complaint is heard that schools for nurses are short from 10 to 50 per cent of their usual quota of student nurses. What is wrong with our schools for nurses that they have not called out from the ranks of young American womanhood sufficient numbers to meet the demands of the present day? Never have there been opportunities for bigger, finer services open to nurses than there are today. This has been brought about by the recent almost unbelievable growth of public health nursing.

There is room at the top of every ladder which women have tried to climb; the lower rungs of some are so overcrowded that many aspirants are pushed off and lost in the jam, but here is a ladder not yet overcrowded, the top rung of which has never been reached. There is no "Keep off" sign posted in masculine handwriting, and no one denies women full access. The ladder's demands, from the bottom rung up, exceeds the supply.

Some reasons for this situation are more marked than others. Among those most frequently accepted are:

(1) There are hundreds of occupations open to women today where twenty-five years ago there were but two. Many of these in less laborious fields offer almost as good remuneration, an eight hour day, and little training.

(2) The exploitation of student nurses and the practice, too often found of using nurses' schools to make money for the institution, has tended to keep the able and intelligent women from entering the profession.

(3) Nursing education has not yet been placed on a par with women's education in other fields. The average training school offers nothing much of educational interest to the young women who have gone through college and to whom an extra two years at a university would give

far more pleasure and an equal earning capacity.

(4) Three years spent in doing hard work, called "training," for which they get their board and at times a few dollars. In too many hospital schools there is very poor training, or none at all, in any of the special fields opening to nurses, such as public health work, laboratory, or secretarial work, executive, and teaching positions, in hospitals, schools, and medical social service. Changes and reforms are undoubtedly needed in the nursing profession, as well as in the medical, educational, and other professions.

The demand for more nurses and more adequate nursing education is being voiced from many groups and has been tremendously intensified since the shortage has been felt in hospitals. There seem to be two groups of critics interested in the present situation. One group, mostly medical men, are declaring that nurses are over-trained; the other group, medical men, sociologists, public health experts, and leaders, are even more insistent that nurses are not highly enough trained to provide the necessary leaders for the great program of health education.

It is quite time the public took an interest in nursing problems and gave help in filling the schools that are giving a good training, because it is not primarily in the interest of the nurses or the hospitals that the knowledge of nurses training schools should be stimulated, but rather it is in the interest of the public; for nursing has become a public concern. The sick public, whether rich or poor, needs nursing service. The well public, whether rich or poor, needs health instruction by nurses. Nurses must be taught before they can teach.

The notion died long ago that education is something every individual should pay for, because it is to his own advantage to be educated. A state school system is a proper charge on public funds. The system recently inaugurated in Kansas City described in another article in this department is a step in the right direction. If a program of intensive training could be put through, and nursing as a profession be put on a proper educational basis in all colleges and universities, there is no reason why the nurses should not pay the usual fees for the instruction that would give an opportunity for nurses to fit themselves thoroughly for every department of work. Certain hospitals could be used as laboratories and proper instructors be provided.

The morale of the nurses will rise to still higher standards as they are treated by hospitals in accordance with established precedent in colleges. Under the present system we trust them with the lives of patients and yet we treat them as if they could not be trusted; we graduate them at the end of three years, although their fitness to continue unsupervised at the end of this period is not demonstrated by any tests of standard.

Young women are everywhere turning away from schools for nurses to colleges because of the better education offered there. The shortage of nurses is not due to the length of the course of training, although many statements are made to that effect.

Women's schools and colleges requiring four years of high school and four years of college to secure diploma are today, as never before, turning away young women because of lack of accommodations, and it is a known fact that our best schools for nurses requiring four years of high school preparatory for entrance and giving a full three years of training are suffering far less from a shortage of students than the schools which have shortened their courses and have lowered their educational requirements.

Nursing is not a call to the ignorant. Its call is to the intelligent, well educated young woman. The work she must do demands brains and scientific knowledge which can only reach their highest development through education. Readjustment and changes in nursing education must come, it is true, but they will be changes which will put nursing education on a par with women's education in other fields. We must raise, not lower the standards to give efficient care to the sick, both rich and poor, in institutions and in homes. EDITOR.

CHILD WELFARE AND THE RED CROSS

Child life everywhere is the immediate concern of the League of Red Cross Societies as expressed in the program outlined at their first meeting at Geneva, held in March. The wide representation of all agencies has given definite form to Child Welfare Work which should become immediately effective everywhere when once it begins to be applied.

An interview reported in the *New York Times* quotes Henry P. Davison, chairman of the Board of Governors of the League as saying:

"The program of the medical conference held at Cannes has become the common possession of the Red Cross societies of some twenty-seven countries. The congress has agreed upon campaign for child welfare which will profoundly affect the health and care of mothers throughout the world. I assume this plan for child welfare will become immediately effective everywhere when once it begins to be applied.

"I feel the same confidence in the effect throughout many countries of the programs we have adopted against tuberculosis, malaria and other diseases. The League of Red Cross Societies will also bring into definite form, and communicate to its organizations, which will bring them into effect, many plans for public welfare which will work of their own force. The impulse thus created will be felt in distant lands.

"One thing which has been grasped and which, I am sure, will have practical results is public health nursing in connection with industrial problems, school life, tuberculosis, maternity and social service. This calling will bring out in women taking it up the finest qualities of enthusiasm, intelligence, devotion and forcefulness.

"The recommended financial policy is for each national society to endeavor to bear its administrative and permanent expenses from membership fees and other regularly assured income.

"Other recommendations cover the employment of properly qualified persons to conduct health service programs and the training of lay workers. The medical program as prepared by Dr. Richard P. Strong, director general of the Medical Department of this league and adopted by the congress, covers recommended practice with respect to treatment of tuberculosis and other infectious diseases, improvement of public sanitation and an earnest endeavor to educate the public along practical health lines.

"Delegates to the congress enthusiastically responded to the appeal of A. J. Balfour, president of the Council of the League of Nations, to call upon the people of the world, through their respective Red Cross societies, to supply doctors, nurses and other personnel, as well as foodstuffs and other materials, for the relief of suffering and destitute people throughout stricken areas, when assured that Governments will provide elemental essentials. This call for voluntary service is of such magnitude that only the Red Cross societies of the world, coordinated through the league, could hope to respond to it in anything like an adequate degree."

To the end of creating an international health agency to carry out relief measures the general medical office of the league has been divided into thirteen departments, each with a separate function. Colonel R. P. Strong, United States Army, has been placed in charge of this office.

NEED OF PROTECTING THE HEALTH OF WORKING CHILDREN

By HAROLD H. MITCHELL, M.D., Special Agent, Health, National Child Labor Committee.

We must recognize the need for protecting the health of the working child as we now recognize the health problem of the school child. It is estimated that at least three quarters of a million children in the United States 14 to 15 years of age leave school each year to engage in wage earning pursuits. These children have almost no opportunity to train themselves for other than manual labor. They are wholly dependent upon their health and muscle to make a living. Neither they nor their parents

A tenement home where the whole family, even the little girls, are engaged in cutting embroidery.

have any appreciation of hygiene or how to maintain their health.

The medical profession generally recognizes that children are more prone than adults to the dangers of exposure to poisons which occur in various industries, that children are peculiarly susceptible to a latent tuberculosis, and that they are, as well, prone to the effects of overfatigue and any general physical strain. The very resiliency of youth may increase the health hazard until the danger line is passed and the young worker has lost his most valuable possession—the ability to work and to earn a living. In short, the working child constitutes a singular public health problem.

We must not yet regard child labor as a health problem that will soon be cared for by legislative prohibition. We have pushed legislation until many of the grosser evils are removed, but even if we should raise our minimum age to sixteen years, we should still have a health program of immature wage earners.

Public health standards and methods are now going farther than the sanitation-bacteriology principles of preventing disease. We are now calling on the hygienist and physiologist.

The child labor health problem involves medical examinations for eliminating the physically unfit and for correcting physical defects. Sixteen states now require the examination of a physician for the issuance of a work permit, but a number of these do not really protect the child, as he may go to any doctor who will state that he is in good health. These examinations should result in the removal of all correctable physical handicaps and such subsequent examinations should be required as are necessary to protect the child from the hazards of his employment. If the child is being injured by his occupation,

Two boys, ten and twelve years of age, are shown gathering rye. These children should be in school. Child Labor Day is an appropriate occasion for giving attention to the problem of conserving the health of the young wage-earner.

the examiner should have the authority to revoke the permit or require the child to change his occupation and to see that the child is followed with the necessary health supervision through a public health nurse, clinic, or private medical attention.

The child's mind is virgin soil for health for health instruction of every sort. In childhood one does not en-

Medical inspection and testing eyes of children. The child labor health problem involves medical examinations for eliminating the physically unfit and for correcting physical defects. Working children must be trained to protect their own energy and health.

counter opposition from prejudice and fixed habits. No child should be permitted to continue in any form of work which prevents his normal growth and development as determined by accepted standards; neither should he be permitted to grow up without learning the fundamental principles of right living. Earlier and more intensive application of the principles of preventive medicine is called for among the children. Health work, therefore, becomes bound up with the problems of general education. Instruct the child properly in health matters and we need have no anxiety about the adults of the next generation.

THE HOSPITAL AS A HEALTH CENTER

By MABEL MONTGOMERY BOORUM, Director, Social Service Department, Mount Sinai Hospital, New York City

TO make the hospital the health center of the community seems a logical proceeding, for the hospital holds the key to the health situation in any community.

One of the first duties of a social worker connected with a community center or settlement who wishes to do constructive work is to see to the health of the people with whom she comes in contact. To improve living conditions and correct physical defects as well as to see that the people are cared for in case of illness—to do this, the social worker refers cases hither and yon to hospitals and dispensaries, wherever the patient will receive the proper treatment and advice.

Use Established Agencies

Many of the progressive social organizations, originally established with a view to non-medical work, have set up independent clinics. This seems a waste of energy and funds and shows a lack of appreciation of the facilities at hand. The hospital and hospital dispensary are there in their midst, established and fully equipped for skillful treatment of disease and capable, under proper guidance, of doing their part in the larger and broader field of prevention. This is, of course, the old argument that the patient does not receive the proper consideration, advice, or treatment in the average dispensary. While this may be true in many instances, if all interests were centered in the hospital, duplication of service under the old method would be obviated and the hospital and hospital dispensary would be raised to the plane of an educational health center.

A survey of the organizations in the district of each large hospital should be made. The function and scope of each should be understood by the various workers in the field. The Visiting Nurse Association, relief agencies, neighborhood houses, and settlements should be encouraged to look upon the hospital and hospital dispensary as a place to which to turn when health problems arise. This would mean many reforms and a much broader conception of what true cooperation means. We have plenty of competition; let us have more cooperation. A plan of organization, closely following the principles laid down by Dr. Michael Davis and Dr. Andrew H. Warner in their valuable book, "Dispensaries—Their Management and Development," might be worked out. We have compulsory education laws; let us hope in the near future we will also have compulsory health laws, with all hospitals and dispensaries raised to such a high standard that the hospital will automatically take its proper place in the community as a health and educational center.

The largest and best equipped hospitals have achieved much in advanced medicine, but it may be well to note that the more scientific the practice of medicine becomes, the more it tends to become impersonal. This utterly impersonal treatment leaves a fatal imprint on the mind of the young intern who is being trained for private practice, and hospitals must guard against this tendency to become machine-like. Group medicine must not be developed to the exclusion of the old fashioned individual or family practice which, whatever its faults, had the merit of keeping the patient as an individual in the foreground. This point of view tends to become lost as the study of medicine reaches a state of complexity which necessitates the cooperation of a whole corps of specialists but whose skill is invaluable as a supplement to, not a substitute for, the sympathetic personal viewpoint of the old fashioned family doctor.

Hospitals to Conserve Health

We have come to the point when we can say that the function of the hospital is no longer exclusively to care for the sick, but to conserve health. In June, 1919, a health class for well children between the ages of two and six was established in Mount Sinai Hospital, with Dr. Ira Wile in charge of the class. We have prenatal clinics, infant welfare stations, and the school nurse to safeguard the health of the child; but very little thought has been given to the child of pre-school age. It was to bridge over this dangerous period of childhood that the health class was organized, in the hope that by careful supervision the children who attend this class will enter school reasonably free from physical defects. The class at present has a registry of 209 children. On an average, forty children and twenty mothers attend the weekly conference. The children are undressed, weighed, measured, and given a thorough mental and physical examination when they first enter. If a child is suffering from physical defects, he is referred to the proper clinic for treatment and, as a reward for being well, is allowed to return to the health class when defects are corrected. The homes are visited by the social worker, who sees that the doctor's instructions are carried out. These visits are of the utmost value, as the social worker keeps in touch with the child and its home life and advises the mother in the proper preparation of food and as to the laws of hygiene. It is difficult to get a busy mother to bring her child to the clinic unless he is really ill. The attendance of our health class proves beyond a doubt that it is possible to interest the parent if she is made to understand the importance of keeping the child well, not waiting until medical treatment is required. The following report on one hundred children, for the first four months of the health class, may be of interest:

Classes held	15
Total attendance: mothers 107, children 359	466
Total home visits made	382
Total visits made to other clinics for cooperative work	167
Total gain in weight of 100 children	241¾ lbs.

Mount Sinai Hospital is most fortunate in having a fund specially donated for preventive medicine, and when our new buildings are completed we are to have a large auditorium for mothers' meetings, demonstrations, and health conferences. The health class for children is the nucleus of a real health center.

When considering the hospital as a health and social center, the first thought that flashes through one's mind is: Are the interns and student nurses being trained to take their place in the community, to preach the gospel of health as well as to minister to the sick? The question is debatable.

There is a crying need for the full use of social service and out-patient departments, by the nursing department of hospital, for the following very excellent reasons: (1) Because the social spirit should not be confined to the social worker; (2) because a nurse is not truly a nurse

until the social spirit is fully developed; (3) because in the social service and out-patient department the student nurse is brought in close contact with the patient before he or she is actually ill, and while illness can be prevented; and (4) because the contact with the individual who is the victim of poverty, bad environment, poor housing, or social conditions presents quite a different aspect from the man or woman in the hospital ward with a very definite illness to combat.

There is a natural tendency on the part of nurses and physicians to think of bed one as a typhoid case, bed two as a pneumonia case, bed three as a case of anemia, and bed four as a neurological case. The disease is the problem in mind, not the individual or the underlying cause of the illness. It is doubtful if a student nurse who has not had experience in either social service or the out-patient department ever gives a thought to the kind of home the patient comes from or to what conditions he returns when convalescent. If a student nurse were given the opportunity to visualize the background of the average ward patient's life her whole viewpoint would be changed and, instead of merely thinking there is no reason for the woman in bed to be nervous, morose, and to show so little inclination to recover, she would set about to discover the cause of the patient's listlessness and lack of interest in life.

The average student nurse comes to the hospital with but a vague idea of what nursing really means. She has visions of holding patients' hands, smoothing fevered brows, arranging flowers, preparing dainties, and making the patient happy and comfortable. The idea of giving personal service is there, with all the disagreeable side of nursing and the drudgery left out. This missionary spirit is allowed to atrophy by constant demands upon the nurses' time, pressure of work and grinding hospital routine. A remedy for this state of affairs should speedily be found. Many of the large hospitals are now considering the eight hour day. This will no doubt help tremendously in the average nurse's attitude toward the patient. Young women who are fatigued by the strain of long hours and work cannot be expected to give much thought to anything but the routine work. I am glad to say that Miss Elizabeth Greener, superintendent of Mount Sinai Training School for Nurses, has succeeded in establishing the eight hour day. This system has been in working order since last October and has been most successful. The nurses work better and have improved physically.

It is most important that the nurse's social spirit should be stimulated from the very beginning of her training, (1) by direct social teaching, and (2) by actual contact with the problems that play such a ghastly part in filling the hospital wards.

It is impossible to estimate the value of social training for student nurses and these young graduates, enabling them to go out in the world with a full understanding of life and its many perplexing problems, as powerful factors in educating the public in its attitude towards vice, poverty, and distress. In the past few years there has been a general awakening to the important part that health plays in the welfare of the individual and the community. Many large hospitals are considering the advisability of allowing the student nurse an opportunity to learn something of the lives of her patients outside of hospital wards.

Scope of Training Broadened

There is no doubt but that in the past the student nurse has been trained in courses that were invariably of value to the hospital and in many instances exploited to a degree, but the old system of training is surely going and training schools must offer a broader course if young women are to be induced to take up nursing as a profession. Training schools all over the country are facing a shortage of student nurses. This is due in a measure to the change of conditions brought about by the war. Women are entering many fields of labor that seem to hold a brighter future, shorter hours, and greater remuneration. To meet the change training schools must be prepared to give a wider opportunity to the student nurse.

Three years ago the Mount Sinai Hospital authorities recognized the value of allowing the student nurse the privilege of training along social service lines. As no definite plan was determined upon, an experiment was tried. Since January 1, 1918, a group of four senior nurses has been assigned to the Social Service Department for three months' training. Each pupil nurse is sent to the different departments in turn and is trained under the supervision of the worker in charge of the department. Short, comprehensive talks on public health and case work are given by the head worker. The pupils also attend the regular weekly committee meetings, when cases are discussed and plans for relief are worked out. Each group is taken to the following places of interest: The Children's Clearing House, Randalls Island School for Mental Defectives, Society for the Prevention of Cruelty to Children, and the Children's Court. Through the cooperation of Dr. S. Josephine Baker, director of the Bureau of Child Hygiene, Department of Health, a day is spent in the public schools with the school nurse, also a day with the nurse in charge of the Infant Welfare Station. A course of six lectures is given each year by men and women well known in the field of social service.

The training of these students requires considerable time and effort on the part of the worker, and just when they become valuable they are sent back to regular hospital duty. We look forward to the time when the pupils sent to us for training are assigned for a period of not less than six months, which length of time is necessary in order that they may not only understand the technic of the work, but develop a proper social vision.

The experiment, on the whole, has been successful. The students grasp the spirit of the work and all have expressed a desire to continue in this field after graduation. At present we have on our regular staff three of the recent graduates who took the social service course. The supervision of the pupil nurses has been as careful and thorough as the pressure of work allowed; however, we look forward to the day when the pupil nurse remains with us for a longer period and when we will be able to have on our staff a worker who devotes all her time to teaching and supervision. Or, if a plan can be worked out to relieve for a period of eight months the student nurses who elect to take up social service work, we hope it may be possible in the future to send them to Columbia College for training. The Hospital Social Service Association of New York, recognizing the fact that the hospital social worker needs training and needs it badly, conferred with Miss Nutting of the Department of Nursing and Health, Teachers College, and a very definite course was worked out. Graduate nurses and student nurses from recognized training schools are eligible to take this course in public health and social service work. Miss Florence Johnson, a member of the Teachers College staff, at present director of the Atlantic Division of the Red Cross, is in charge of the field work. We feel that this course at Columbia opens up a very wide field and that a new era for social service is at hand.

HOW KANSAS CITY EDUCATES NURSES

By HELEN FARNSWORTH, Instructor, Junior College for Nursing Education, Kansas City, Mo.

IN the summer of 1918 the nurse instructors of the Department of Nursing and Health of Teachers College, Columbia University, Misses Isabel Stewart and Pamelia Doty, talked to their summer session students of the necessity of higher education for the nurse and the advisability of training schools for nurses affiliating with universities and colleges. A student from Kansas City, realizing such a need was acute in her locality, drew all the assistance possible from the instructors at Teachers College and returned home, intent upon adapting this theory to Kansas City's possibilities.

Public Schools Meet Public Need

An interview with the superintendent of public schools, Mr. I. I. Commack, disclosed his interest in nurses' education, but the details he turned over to the principal of Kansas City's one center of higher education, the Junior College. The principal, Mr. E. M. Bainter, had just returned from government service in Porto Rico, where he was in charge of the school system, and was keen for advancement. Immediately the appeal was made to him to throw open the doors of the College to nurses, he evinced an interest and understanding that surmounted every problem. He assured the Kansas City League of Nursing Education, which sponsored the plan, that he would help in every way possible. In the few months that followed the plans were formulated, the Board of Education appealed to and, thanks to Mr. Bainter's tact, discernment, and wisdom, the members of the Board grasped the idea that the education of nurses was just as much within the responsibility and jurisdiction of the public school system as was the education of the school teacher, the lawyer, physician, or business woman.

The plan was to have the preliminary course, as authorized in the standard curriculum for nurses, taught in a twenty weeks' course of two hundred eighty hours' work in the College,—two courses each year to correspond with the semesters of the school year. The College instructors were to teach anatomy and physiology, sixty hours; bacteriology, twenty hours; chemistry, twenty hours; and cooking and nutrition, forty hours; all of which included laboratory work with excellent facilities. Four nurse instructors from various hospitals consented to teach the additional subjects: hygiene, twenty hours; drugs and solutions, twenty hours; ethics and history of nursing, twenty hours; and practical nursing, sixty hours. The Board of Education, through Mr. Bainter, arranged that the nurse instructors should receive the pay per hour allowed other teachers of special subjects. The hospitals sending students paid a nominal laboratory fee of three dollars per student for all laboratory fees, and paid a small amount to supplement the sum paid the instructor in practical nursing, who gave considerable extra time. The hospitals were also requisitioned for beds, bedding, utensils, Chase dolls, and other equipment for a demonstration room which was fitted up in a large class room at the College.

Accredited Schools Matriculate

The League of Nursing Education established the standard for admission to the course. Any accredited training school could send students, provided their educational requirements and age were reached. Each hospital had to agree to room and board its own students, arrange for car fare, and give only four hours on duty to the students, as probationers. Hours on duty to be seven to eleven A. M.; in college, one to four P. M., and the rest of the time to students for study. An educational committee from the League inspects the credentials of each student before admission and keeps supervision of the teaching, calling the superintendents of each training school together from time to time for consultation.

In the practical nursing the instructor, Miss Anna Belle Murphy of the Christian Church Hospital, held weekly conferences at the College the first semester, attended by the practical instructors or, in lieu of one, the superintendent of nurses of each hospital. At this conference methods of procedure were discussed; systems compared; and a common plan acceded to by all. Miss Murphy then demonstrated each procedure before the Conference, in order that each training school representative could go back and supervise practice periods of her pupils. Instruction cards were then made out by Miss Murphy and supplied to each student and each training school. In this way a great step towards standardized equipment and procedures was taken.

The course opened in September, 1919, with thirty-eight students enrolled from five hospitals; namely, Christian Church Hospital, Mercy Children's Hospital, St. Luke's Hospital, Swedish Hospital, and Wesley Hospital. Two other training schools applied too late for the first course. Thirty students completed the course, and late in January, 1920, received the credits that enabled them to enter upon the Junior work in their respective training schools. The second class to be admitted was enrolled immediately, with twenty-one students representing, in addition to the above named hospitals, the Bethany Hospital of Kansas City, Kan., and the Research Hospital. All these students remained to complete the course and receive their credits.

Pioneer Work in Public Education

In many ways the course can be strengthened for the coming year of 1920-21; but all agree the work is of great value. To the hospital it is a relief from an educational burden superimposed upon their primary duty of care for the sick. The students have profited by the College contact and atmosphere, and a breadth of view was attained from so many well prepared instructors; and they have also the realization that they in truth received a higher and special education, which placed them at once in an enviable position among the other students in nursing schools. Not the least of the advantage is to the College itself. To Mr. Bainter and his corps of instructors has come the satisfaction of doing a pioneer work in a field so necessary and of such practical application as that of the nurse; while the enthusiastic support of the Kansas City League of Nursing Education, with its program of publicity, is calling for newer buildings, added equipment, and more instructors to enable this splendid educational center to reach wider fields of usefulness in Kansas City and its vicinity. This program includes a Central School for Nurses to take over not only the present preliminary course, but the later and special theory necessary for the complete education of the nurse.

KANSAS CITY MEETS NURSE PROBLEM

The Kansas City Junior College for the nurses' preliminary course is a pioneer among municipal public schools in offering necessary theoretical sciences to nurses in training in hospitals. The courses designed for them under the regular school instructors include the fundamentals of drugs and solutions, the history of nursing, physiology, chemistry, bacteriology, anatomy, cooking, and hlgiene. This method of training will attract to the profession young women not otherwise to be interested.

PROBLEMS IN SOCIAL MEDICINE

JOHN A. LAPP, LL.D., *Editor*

THE VENEREAL DISEASE CAMPAIGN IN NORTH CAROLINA

NORTH CAROLINA is considered to have one of the most thoroughly organized health departments, and its activities along the line of venereal disease control have been of equally high standard. A recent issue of the *Health Bulletin* published by the State Board of Health contains an excellent description of the venereal disease menace and the methods pursued by the Bureau of Venereal Disease in combating this menace.

An interesting reference showing the effect of the venereal disease problem in its relation to child life and reproduction is contained in an article by Dr. Millard Knowlton, chief of the Bureau of Venereal Disease.[1]

In a study of syphilis in relation to infant mortality Dr. P. C. Jeans of St. Louis concluded that from 10 to 20 per cent of adult males and 10 per cent of married women are syphilitic; that 75 per cent of the offspring of syphilitic families are syphilitic; that 30 per cent of pregnancies in syphilitic families result in death before term, as against the normal rate of 10 per cent; that 30 per cent of living children in syphilitic families die in infancy; that 25 to 30 per cent of syphilitic infants die of syphilis; that but 17 per cent of all pregnancies in syphilitic families result in healthy children who survive infancy; and that about 5 per cent of all infants are syphilitic.

In North Carolina as many as one thousand cases of venereal disease are reported monthly by physicians to the Bureau of Venereal Disease, while druggists have reported as many as two thousand sales of venereal disease remedies per month. A very significant fact is that about one-half the cases of infection are innocently acquired, and nearly all the innocent victims are women and children. "Surely no one," says Dr. Knowlton, "would wish to have innocent women and children suffer unnecessarily for the conduct of the husband and father; yet this is exactly what has happened as a result of our past attitude toward venereal disease. The modern view that such disease is incidental to sex irregularity, rather than a punishment therefor, has resulted in an entirely different attitude towards infected persons."

The three main lines of activity in the campaign to combat venereal disease are medical measures, including the treatment of infected persons to render them noninfectious, resorting to quarantine when necessary; repressive measures against prostitution, which is considered a great source of venereal disease; and the educational measures for the purpose of disseminating accurate information concerning venereal diseases and arousing the public to adopt vigorous methods for their prevention.

JULES SCHEVITZ.

COORDINATION OF CHILD HEALTH ACTIVITIES

ORGANIZATIONS doing health work among children are more and more coming to appreciate the pressing need of correlating their activities. Not only is there much duplication and, therefore, much waste of effort; but it is felt that many opportunities for developing well rounded programs for the health of children are thus lost.

The American Child Hygiene Association, American Red Cross, Child Health Organization of America, National Child Labor Committee, and the National Organization for Public Health Nursing have held several conferences with a view as to how such correlation may best be effected.

As a result, the representatives of these organizations have formed a Council for Coordinating Child Health Activities, to which will be added gradually other national organizations carrying on well defined programs for the health of children. The main objects of the Council are: (1) To define and develop so clearly their own work that each organization will be working in harmony and cooperation with all the others; (2) to develop new methods which will lead to meeting more effectively some of the special problems still unsolved; and (3) to afford an opportunity for any organization dealing with the health of children to submit its plan and program for suggestions.

This action, which bids fair to be a long step in the coordination of child welfare activities, is to be highly commended. The widespread interest in child welfare, and especially in child health measures, has brought into being scores of organizations, local, state, and national, which have been working with earnestness and zeal for the benefit of the child. Many of these efforts have been handicapped for lack of funds and by their failure to coordinate their work with other activities. There is much work to be done and no organization need fear that opportunities will not be at hand. Beginnings only have been made in the movement for effective child welfare work. Many untouched fields and many half developed fields of physical, mental and moral care of children remain untilled. It may be confidently expected that with coordination and cooperation the boundaries of child care may be extended.

S. P. M.

ILLEGITIMACY AS A CHILD WELFARE PROBLEM—A REVIEW*

By HUGO EHRENFEST, M.D., St. Louis, Mo.

THE report of the Children's Bureau under their Publication No. 66, presents a survey of available statistics and literature relating to the prevalence of births out of wedlock both in foreign countries and the United States, discusses the status of the illegitimate child and records the various measures of protection and guardianship by which public and private agencies have attempted to mitigate the obvious handicaps of the illegitimate child. In an appendix a complete bibliographical list of the source material for this report and of general references is given.

Problem in European Countries

Differences in laws and customs, and in methods of securing and compiling vital statistics in various communities and countries, render a comparative study of the statistics of illegitimate births very difficult. Two methods of computing illegitimate rates are used in this report: the first gives the proportion of illegitimate births to total births in a given period; the second compares the number of illegitimate births with the number of single, widowed and divorced women of childbearing age in the respective community. The first method emphasizes the extent of the child-care problems involved; the second gives data relating more definitely to causative factors and to the moral and preventative side of this problem.

European birth statistics, because of their importance in connection with obligatory military service, are very complete and reliable. A comparison between the legitimate live births for every one thousand married women between the ages of fifteen and forty-nine years and the illegitimate births for an equal number of single, widowed, and divorced women of the same age shows wide variations in the various countries, and even in political divisions of the same country. The number of legitimate children per thousand married women ranges for Europe between 114 and 250, of illegitimate children between 4 and 38 for one thousand unmarried mothers. Racial differences, economic and social conditions, marriage customs, laws, constructive social influences, and various legal provisions in regard to the status of the illegitimate child account for the variation. During the past thirty to forty years only in France and Sweden the illegitimate birth rate has fluctuated or increased; in Ireland it has remained stationary; in all other European countries it has decreased.

Recent English statistics prove that a decline in the total birth rate is likely to result in a rise of the percentage of illegitimate births, though in fact the number of the latter group actually may not have increased.

In large centers of population social problems are more intensified. Greater opportunity for better maternity care causes the illegitimate cases to gravitate to the larger cities. The result is clearly shown in a comparison of the percentages of illegitimacy in large cities with those of the entire population. Thus Stockholm records a percentage of 33.5 of illegitimacy, Vienna 30.1, Paris 25.5, Berlin 18.1, Rome 16.5; while the annual average of illegitimacy for the German Empire is 8.7, for France 8.9, for Austria 12.3, while in England the total average of 4 per cent indeed is higher than the percentage of illegitimacy in London at 3.5.

Conditions in the United States

The inadequacy of birth statistics in the United States is evidenced by the fact that for only sixteen states, and for only twenty of the sixty-two cities with a population of more than 100,000, figures on illegitimate births could be obtained.

On the other hand, it is necessary to treat the figures for the negro population separately, since illegitimacy among negroes must be studied by itself in its relation to the social and economic conditions surrounding the race at the present time and in their past history. However, it is most noteworthy, that, quite different from the white population, among the negroes a child born out of wedlock, as a rule, has very much the same advantages and disadvantages as a child born in lawful marriage. There were not enough data available to study adequately the problem of illegitimacy among the negroes.

The average legitimate birth rate per thousand married white women was found to be 180.7, the average illegitimate birth rate for one thousand unmarried white women 4.3, with not very wide variations in these figures in the different states.

An analysis of the relation between illegitimacy rate and the percentage of unmarried women among all women of child bearing age revealed

*A digest and analysis of the report by Emma O. Lundberg and Katharine F. Lenroot, United States Department of Labor, Children's Bureau Report, Publication No. 66, Washington, D. C.

considerable differences. Thus in Vermont, where the illegitimate birth rate was relatively high, only 40.2 per cent of the women of child bearing age were unmarried. The percentage of illegitimacy among the total births of the states studied was 1.8, being a little higher than this average in the 5 New England states. Excluding the negroes the illegitimate percentage in the larger cities ranges between 6.1 (Kansas City) and 1.2 (New York City). Although all available statistics are meager, the total number of illegitimate white births for the United States can be estimated approximately as 35,100.

Relation to Infant Mortality

Most European countries recognize the evident relation between illegitimate birth and infant mortality, and furnish comparative statistics. The mortality of infants born out of wedlock without any exception is higher than among other infants, ranging from 1.3 to 2.3 times that found among legitimate infants. The countries having the lowest infant mortality among legitimate children also show the lowest mortality for infants borne by unmarried women.

With the exception of full statistics for German cities, little information is available in regard to comparative mortality rates of infants of illegitimate and legitimate births in cities. All available figures show a constant and marked decrease in infant mortality, presumably as the result of special protective efforts. Some of these cities have actually lowered infant mortality for the illegitimate below that of the legitimate for the entire country.

Figures on comparative mortality rates for infants born out of wedlock in the United States are not obtainable for the country as a whole, or for any individual state. The alarming conditions that may be disclosed by an analysis of infant mortality statistics in this country are indicated in the figures secured in a study of illegitimate births in Boston, and the situation discovered in the study of infant mortality in Baltimore. In Boston (in 1914) the mortality among legitimate infants was ninety-five for every one thousand, while infants born out of wedlock died within the first year of life at the rate of 281 per one thousand. In Baltimore the rate for white legitimate children was 95.5 per one thousand, and for white illegitimate children 315.5 per one thousand.

Status of the Child

Extra-marital unions throughout civilized time have been held to be inimical to the interest of society and of the children born as the result of such relationship. Gradually the social and legal theory developed that the children, at least, are innocent of wrongdoing and that they are entitled to the benefits commonly enjoyed by legitimate children. Recent social legislation in the United States has either specifically or by implication included children of illegitimate birth within the scope of their provisions. This applies especially to benefits under workmen's compensation acts. There is a tendency observable of the courts to hold that illegitimate children should not be made to suffer for the wrongdoings of their parents. Mothers' pension laws in some states explicitly or impliedly include children born out of wedlock, but are still excluding them specifically in the laws of twenty-nine states (1913). The Federal Act providing for allotments and compensation to dependents of soldiers and sailors includes illegitimate children among the beneficiaries if support has been ordered by the court, or if the child has been acknowledged by the father. Recent laws of some states, compelling paternal support both for mother and child, are characterized by their emphasis of making the welfare of the child the predominant consideration.

The laws of the Scandinavian countries are recognized as setting standards far in advance of those prevailing in most countries.

Protection and Guardianship

The earliest provisions for the protection of the child were occasioned by the prevalence of infanticide due to abandonment. The unmarried, ostracized mother often was unable to provide any care and abandoned her child. The first foundling asylums were started by the church as early as the sixth century. Gradually, however, it became obvious that the protective effect of such institutions was more than outweighed by the notoriously high infant mortality of all asylums in which infants are kept in close proximity in large numbers; but not until the beginning of the twentieth century did this system begin to be largely displaced through the granting of aid to mothers to enable them to care for their own children and, through the development of the principle of boarding out younger children, under guardianship of the state, in country districts. This modern system is now quite generally practised in Europe.

In the United States foundling asylums are still common in the large cities. In the best of these institutions an effort is made to keep the mothers with their infants and also to use them as wet nurses for abandoned infants. Later the children are given out for adoption or otherwise, often with very inadequate protection. Studies of the mortality among infants placed in such institutions have revealed an alarming situation, but improvement in this respect is noticeable.

A better appreciation of this problem is evidenced in the recent appearance of maternity homes which provide not only proper care during labor, but also provide the mother with necessary attention and assistance during pregnancy and a considerable portion of the nursing period, giving advice, and continuing supervision after discharge from the home. A few special agencies assist the mother to find a home and to care for her child, securing for her such employment that she can keep the child with her. In a number of cities of this country the system of home visiting for the purpose of following up registered births is in use, but this rarely includes the cases of illegitimate birth.

In England a recently organized National Council for the Unmarried Mother and her Child contemplates the establishment of special hostels for these mothers. The effect of war conditions in emphasizing the importance of public protection of infancy is also seen in France, where the period of financial assistance to the illegitimate mother has been extended from two to three years.

The history of the child welfare movement shows that the state everywhere is becoming increasingly active in taking measures for the protection of children who for one reason or another are not given proper care by their parents. It seems, especially from recent German legislation, that one of the chief functions of the public guardian is to secure support from the father. Most of the European countries now possess or are preparing adequate regulations of state's guardianship, which practically without exception includes the illegitimate child.

In the United States, with the exception of Minnesota, the supervision or guardianship of the state over children born out of wedlock occurs only as an incidental feature of state control or supervision over agencies or institutions caring for dependent children. Solely the law enacted in Minnesota in 1917 places upon the state more definite responsibility for the welfare of the children borne by the unmarried.

In the United States the handicap of the illegitimate child is defined almost entirely by the lack of normal home conditions, rather than by any civic or social disabilities. The child of illegitimate birth often suffers great injustice through being deprived of the care that is his due. Society is forced to bear a burden that properly belongs to the child's parents. Heretofore religious sentiment has largely ruled in the treatment of these cases and therefore, as a rule, emphasis has been placed upon saving the mother from the social consequences. Often the liability of the father for the support of the child has been overlooked. With the growing concern of the social agencies to render permanent help and to deal in a larger way with the whole problem, it is now being considered from a new angle, with the child as the central factor. Social agencies in this country have just begun to question whether society has not a peculiar responsibility towards these children, who from birth are deprived of the advantages of normal home life.

Comment of the Author

This change of point of view has made this entire problem a strictly medical one. Therein lies the importance of this report for the medical profession of this country. To be true, it deals only with the illegitimate child. It culminates in the final conclusion that the state has a definite responsibility to offer also to the illegitimate child those opportunities commonly enjoyed by the legitimate child, which enable him to survive at least the first year of his life. This is really all that is implied in the term "infant mortality." These greater opportunities of the legitimate child undeniably in the main consist in prenatal care and proper medical attention available for the mother during confinement, and in the proper feeding of the infant.

Are there really taxpaying citizens or legislators left in this country who would willingly deny such inalienable rights to survive to the illegitimate or any other child? To those familiar with European methods of handling this problem and acquainted with recent developments in the United States a report of this sort, though full of interesting facts, would seem superfluous—the necessity for its publication deplorable. But how disheartened must we obstetricians feel who are already endeavoring to convince the public that also the child of the poorer and even of the middle class of this country has the intrinsic right to all those advantages which at present are benefiting the illegitimate children in Europe and only the richer ones in this country.

STANDARDIZE HOSPITAL RECORDS

Of paramount importance in the composite picture of better medicine is the question of the standardization of our hospitals, says Dr. Edward F. Zigelman in the May issue of *Northwest Medicine*. The standardization of hospitals is the natural sequent of the standardization of the medical schools.

The taking of a proper history, both personal and physical, is the obligation of the physician. It is the duty of the hospital to furnish all possible aid in diagnosis and treatment and the hospital has a right to demand in return from the physician detailed records of the case and the results achieved. The checking up of end results becomes the practical test of efficiency. It is the manifest duty of the whole profession to promote the keeping of complete, concise records on the basis of which the hospital can be classified.

THE PROBLEM OF DISEASE*

From a report by the Public Health Committee of the New York Academy of Medicine, New York City.

WHEN analyzing the rates of prevalence of illness by partial and complete incapacity, we find that, while the two rates run in a way similar to each other, they show the highest prevalence in the third group (C), that is, where the income is from $6.51 to $8.50. Although the per centage of families in that group affected by illness was smaller than in the two preceding groups, yet, because the number of persons in the third group was smaller per family than in the other groups, and perhaps because of their better economic condition more wont to notice illness, their rate of illness per 1,000 individuals is higher than in the other two groups. It is to be remembered that during 1918 we had the epidemic of influenza which, because of its universal distribution, had in all probability disturbed the normal distribution of illness among the economic orders.

There exists a very definite relationship between economic status and the number of maternity cases per 1,000 families in each of the economic groups. The largest number, 265 per 1,000, occurred in the least prosperous group, and the smallest number, 115, in the most prosperous group. Although the rates of maternity are not figused, as they should be, on the basis of one thousand women of child-bearing age, because the ages of the people of the survey were not ascertained in a large number of cases, they are, in spite of inaccuracy in each particular instance, of distinct service for comparative purposes with regard to the comparative fecundity of the several racial and economic groups studied in this survey. The differences in the rates of maternity cases per 1,000 families among the several nationalities are very marked. While the average rate for all groups was 191 per 1,000 families, it was 339 per 1,000 for the Slavs; 228 per 1,000 for the Italians; 191 for the Hebrews; 161 for native born, and 108 for the Germans. The low rate among the Germans was probably due to the fact that the average age of the families was higher than in the other racial groups.

The Treatment of Illness

Of the 8,645 persons in the 2,023 families visited, 3,140 were reported as having suffered from 3,536 illnesses, during the year 1918, making an average of over one illness per person. This includes partial and complete disabilities. Of the total number of illnesses, 1,289 were cases of influenza. Barring influenza from immediate consideration, the rest of the amount of illness may be taken as representing the normal annual sickness problem of the families. In order to meet it the following types of treatment were employed by the families of the survey: 11.6 per cent of the cases of illness went to a hospital; 13.2 per cent of the illnesses were treated in dispensaries; 37.7 per cent consulted private physicians: 4.1 per cent, lodge doctors; 0.8 per cent, a visiting physician from an institution; 10.8 per cent called a midwife; and 23 per cent consulted a druggist or indulged in self-medication.

In Table VIII the type of treatment employed is shown according to the nationality of the families. In studying this table, it is to be remembered that it includes the cases of influenza which constituted 37.4 per cent of all the ailments recorded, and which were omitted from the preceding discussion. With this in mind, it will be readily seen that the figure of 8.8 per cent, as reported for the total number of illnesses treated in dispensaries, it greatly underestimating the part played by the dispensary. If the influenza cases be eliminated from the count, the percentage is 13.2 per cent. The least use of the dispensaries was made by the Slavs, who used for only 14 out of 661 the dispensary cases of illness, or 2.2 per cent. Next in order were the Italians, who used it to the extent of 3.1 per cent; the miscellaneous group used it in 7.3 per cent of cases; the Germans went to the dispensary, in only 9.3 per cent of cases; the Hebrews in 12 per cent; Negroes, 12.9 per cent; the native born, 16.6 per cent; and the Irish, 19.1 per cent of instances.

Racial Distribution

In the hospital distribution of cases the Slavs, Italians, the native born, the Germans, and the miscellaneous group showed a small relative use. It was highest among the Hebrews, the Irish, and the Negroes. Of all the races, the Hebrews and the Negroes used the hospital most in maternity cases, the Slavs and Italians least, and, accordingly, the use of the midwife is the highest among the latter two racial groups of our population.

With regard to the employment of a private physician, the Italians show the largest percentage, followed by the Slavs, Germans, and Hebrews. All of these groups employed a private physician in more than 50 per cent of cases of illness, while the native born did so in about 42 per cent of cases, the Negroes showing a similar percentage. The least amount of service of private physicians was shown among the Irish families.

The greatest use of the lodge doctor was made by the Hebrews, and then by the Germans and Italians. Of the 22 visits made by visiting physicians from institutions, 10 were to native born families, 5 to Hebrew, 3 to Irish, and 4 to Slav families. Eleven of these were maternity cases, 6 were influenza, 1 bronchitis, 2 colds, 1 tuberculosis, and 1 heart disease.

*The third of a series of three articles on dispensary service appearing in MODERN MEDICINE.

The largest inclination to seek non-professional care was exhibited by the Irish, who used patent medicines or tried some sort of self-medication in 34.5 per cent of cases of illness; the least amount of that attitude was shown by the Hebrews, who resorted to self-medication in only 7.6 per cent of instances. The Italians follow the Hebrews very closely. For more than one-fourth of their recorded illnesses the native born group and the negro group used patent medicines and the like for the self-treatment of their conditions.

With the elimination of influenza the percentage figures are changed, but the tendencies in the several directions remain unchanged, as shown by Table VIII. Incidentally, Table VIII presents the distribution of influenza among the radical groups, showing the highest rate of prevalence

among the Italians, Hebrews and Slavs, and the lowest among the Negroes.

Predilections in Medical Care

While there evidently are distinct racial predilections for types of medical care, no similar definite division is discernible among the several economic groups. In Table IX the available information is tabulated by the economic group. Resort to hospitals for both general medical and surgical conditions is greater in the lower economic orders than in the higher. There is evidently no relation between maternity hospital treatment and economic status. There is, curiously, no apparent correlation between the employment of private physicians and income. The two groups which show the largest percentage of consultations with private physicians are groups C and D, on incomes, respectively, of $6.51 to $8.50 and $8.51 to $10.50, while the lowest economic group and the highest two show respectively a smaller percentage of cases treated by private physicians. The employment of the midwife is in inverse ratio to the economic status of the family. The largest relative number of families employing midwives was found among those who received the least income, and it declines as the income increases.

The 387 cases of childbirth that occurred in 1918 among the 2,023 families which were studied were taken care of in the following manner: 11.6 per cent were delivered in hospitals; 22.9 per cent by private physicians; 61.8 per cent by midwives; 2.8 per cent by visiting physicians from hospitals; 1 case was unattended, and for 2 cases information as to care was not obtainable. As has been pointed out in another connection, the largest percentages of

cases delivered by midwives were among the Slavs and Italians; 87.5 per cent of the cases in each of these groups were taken care of in that way; 22.7 per cent of the cases in the native born families were under midwife care. The Negroes and the Germans had one-fourth each of their cases handled in that way; about the same percentage of Hebrew cases employed midwives, and the Irish showed the lowest figure in that respect (Table X).

In all instances, women were questioned with regard to care at their last confinement, irrespective of when it occurred. On the basis of the information obtained we have been enabled to prepare for these families a sort of historical retrospect with reference to the care received during and prior to childbirth. The table (Table XI) shows a growing tendency toward larger hospitalization of cases, a practically stationary condition with regard to the employment of midwives, and a slight decrease in the proportion of private physicians in attendance.

No definite deductions can be drawn from the figures with respect to prenatal, postpartum and nursing care. The figures are too irregular to exhibit any definite tendencies. The highest proportion of cases receiving prenatal care was reported for 1918, but the highest figures for postpartum care are for the years 1911 to 1912, and for nursing care, 1909 to 1910.

The borough distribution of the data on type of treatment of disease employed brings out several points of interest. The largest use of the dispensary is made in Manhattan, twice as many families per hundred resorting to it in Manhattan as in Brooklyn, for example. In the other boroughs, the dispensary was used by still smaller percentages of families. Differing only in proportion, the same applies to the use of hospitals in the several boroughs. Conversely, the services of private physicians were used least in Manhattan in the maternity cases, as well as in all other conditions (Table XII).

The illnesses which were reported in the families during the year 1918 have been classified by as accurate diagnosis as could be applied to the descriptions and designations given by the families. The diseases were classified by groups and tabulated so as to designate the type of treatment each condition had received. Although the designations were frequently very loose, it was possible to bring up the nosology to fifty-six items, although in several instances broad categories were employed.

The results of this study are interesting in several respects, one of them being the marked difference in the proportion of influenza and of pneumonia cases reported as having been taken care of in hospitals. Of the 1,289 cases of influenza reported, more than three-fourths were treated by private physicians, and less than 2 per cent in hospitals; while for pneumonia, although the percentage of employment of physicians was the same as for influenza, more than 14 per cent of the cases were treated in hospitals. Only 7.6 per cent of common "colds" were treated in the dispensary; the remainder of the 474 cases consulted private physicians in 38.6 per cent of the cases and in 48 per cent of the cases employed self-medication. Of the tonsillitis cases, more than one-fifth went to the dispensary for treatment, and the persons suffering from digestive disturbance resorted to the dispensary for only 14 per cent of such illness, while in more than 64 per cent of instances they sought the service of a private physician. It became apparent that the tendency is very definite toward hospitalization of certain diseases, irrespective of economic conditions.

LAW FOR THE DOCTOR*

By LESLIE CHILDS, Attorney at Law, Indianapolis.

The Right of Physician to Rate Himself Relative to His Professional Standing, for the Purpose of Determining Amount of His Fee.

IT has been generally held that a physician, in the absence of a custom of his own, is entitled to compensation for professional services in accord with charges usually made for such services by other physicians of similar standing. And, in rating himself, the physician has the right to claim standing in the class to which, in his opinion, he properly belongs. If his charges are contested on the grounds that he has rated himself too highly, the burden of proving this rests upon the contestant; and, in the absence of evidence to the contrary, the physician's own valuation of the value of his services will stand.

A case on this point, in which it was sought to reduce the charges of a physician on the grounds that he was a young practitioner, and as such had no right to the fees charged by those who were older and whose reputations were established, was that of Re Percival, 137 La., 203. The facts surrounding the case were considerably involved and have been greatly abbreviated, but in so far as material to this discussion were substantially as follows:

For some time prior to April 20, 1914, Miss Mary Percival, a wealthy resident of the city of New Orleans, had been attended professionally by an eminent neurologist. Miss Percival, not being altogether satisfied with his treatment, requested Dr. John T. O'Ferrall to take charge of her case. Dr. O'Ferrall thereupon began attending her on the above mentioned date and continued in charge until June 20, 1914, when Miss Percival died.

Thereafter Dr. O'Ferrall presented a bill for $1,500 for his services which the executor of the Percival estate declined to acknowledge, and the doctor filed an opposition to the executor's account. The case was tried in the district count and a judgment for $262 was rendered in favor of the doctor. From this judgment Dr. O'Ferrall appealed to the supreme court.

As the principal reason for refusing to allow the doctor's claim for $1,500 was based upon the fact that he was a comparatively young practitioner, considerable evidence was allowed into the record bearing on his training and experience. Relative to this Dr. O'Ferrall testified, without contradiction, as follows:

". . . That he was graduated from the medical department of Tulane University of Louisiana, in 1908; that he attended the Army Medical School in Washington City, from which he was graduated in 1909; after which he paid a short visit to New Orleans, and then served four or five months in Bellevue Hospital, in New York; that he then returned here and served five or six months as the assistant of Dr. Van Wart of this city, and then went to Winser, Miss., where he was engaged in the general practice of his profession for two years and a half, with the idea, however, of specializing in orthopedics; that he went from Winser to Boston, Mass., where he entered the Massachusetts General Hospital in which he remained for a year, when he was graduated from the orthopedic department; and that he then spent four months visiting the important orthopedic clinics in Italy, Germany, France, and England, following which he returned to this country, and came to New Orleans in April, 1914."

Relative to the services rendered by Dr. O'Ferrall the evidence showed that he took charge and treated the case exclusively and most assiduously from April 20 to May 22.

*The fourteenth of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

During which period he made two or three visits each day, varying in length from half an hour to several hours. He also made a number of mechanical appliances, known as "Thomas Collars," took a blood test, accompanied his patient to see an x-ray specialist, and generally devoted himself to the case.

On May 22, being unable to determine whether the disease was orthopedic or neurological, or both, he advised that another specialist be called. His advice was taken and he called Dr. Hummell. Later, in consultation with Dr. Hummell, it was agreed that a surgeon should be called and an operation performed. The surgeon was called and advised that the patient be removed to Touro Infirmary. Dr. O'Ferrall attended to the hospital arrangements and the patient was taken there, on June 10, after which the surgeon performed two operations with an interval of about a week between them. On June 20, after the second operation, the patient died.

Evidence bearing on the charges made by other specialists who treated Miss Percival showed that during the two months that Dr. O'Ferrall had charge of her case an eminent neurologist, Dr. Hummell, and a distinguished surgeon, Dr. Matas, were called in consultation, and rendered certain services. The bill of Dr. Hummell amounted to $1,875, and that of Dr. Matas to $1,250; both of these bills being paid without objection.

In passing upon the points raised in the record, and in particular on the cutting down of Dr. O'Ferrall's claim because he was a young practitioner, the supreme court, among other things said:

"Our learned brother [the trial judge] was also of opinion that a young practitioner has no right to charge, or expect to be paid, the fees charged by those who are older and whose reputations have been established, and hence he allowed opponent [Dr. O'Ferrall] but three dollars each, for day visits, and six dollars for night visits, although, according to the evidence, the customary charges by specialists appear to be five dollars and ten dollars, respectively. It may happen, however, that the knowledge of the schools goes beyond that upon which reputations have been founded, and that the later graduate, bringing, with his diploma, the latest discoveries, is more competent to deal with a particular case than the earlier, with the experience of a past generation. However that may be, any physician has the right, in the absence of a custom of his own, to charge for his visits, day or night, at least the fee sanctioned by the custom of the community in which he lives; nor is he obliged, in so doing, to rate himself below the class to which, in his opinion, he properly belongs; and in such a case the burden rests upon the patient who refuses to pay to show a better reason for such a refusal than that the physician is comparatively fresh from the seats of learning. It is therefore ordered that the judgment appealed from be amended by increasing the amount to be allowed to the opponent [Dr. O'Ferrall] to $1,500, and, as thus amended, affirmed, at the cost of the succession."

MILITARY AND CIVIL HYGIENE

In commenting on the delivery of the Chadwick lectures by Sir John Goodwin, Director General of the Army Medical Service, a recent issue of the *Lancet* states that if there is any one thing more clear than another it is that the practice of hygiene in a civilian community cannot be imposed by an edict, but can only be built up on a basis of individual enlightenment. Education is the chief and in the final issue the only effective instrument of civil hygiene.

Military hygiene, with aims and objects precisely similar, deals with a disciplined populace and an organization which permits of action for the community as easily as for the individual. For this reason military hygiene has made progress vastly greater than civil hygiene, as evidenced by greatly reduced mortality rates cited in very able summaries of past and present hygiene.

The last of the three lectures, on "Army Hygiene of the Future," brings together military and civil hygiene in which perhaps the most urgent and timely hygienic lesson of the war is stated to lie in the efficacy of simple materials used in an intelligent way. The lives of regiments were saved by the use of empty tins which a local sanitary authority would have consigned to the refuse heap. Small sanitary authorities, knowing nothing but their inability to afford costly apparatus, should be roused to action. The presence of soldiers drilled year in and out in the elements of hygiene should stimulate this sometimes thankless work which should yet bear fruit in a healthy countryside.

BOTULINUS POISONING

The United States Department of Agriculture have issued information concerning botulinus poisoning due to the consumption of ripe olives. According to the Department, "The experts agree that the trouble is not inherent in the type of container used. Whether the olives be packed in glass jars or in the cans, they may be rendered absolutely safe if proper precautions are taken to prevent the infection with bacteria during handling, and if the packages when filled are sterilized at a sufficient temperature and for a sufficient period of time. It is entirely practicable, say the specialists, to sterilize both glass containers and tin cans at a temperature high enough to insure absolute sterilization.

"Unfortunately some packs of ripe olives put up in glass, as well as some in tin, during past seasons were not prepared with all the precautions now known to be essential, and were not sterilized at a sufficiently high temperature, and some of these goods in glass were responsible for the fatalities. It is probable that of all the ripe olives on the market but an extremely small number actually contained *Bacillus botulinus*.

"Since there is a possibility of danger from any ripe olive which has been insufficiently sterilized, the Bureau of Chemistry has suggested to the industry that all ripe olives in glass or in tin, wherever located, be carefully inspected and that any which show the slightest degree of decomposition be destroyed. It has further suggested that all ripe olives which have not been processed at a sufficiently high temperature be returned to insure complete sterilization. With few exceptions the olive packers have most heartily fallen in with all suggestions made in the interest of public safety and by mutual agreement entered into by practically all of the packers they are now taking steps to withdraw from the market all ripe olives in glass containers which has not been sterilized at a sufficient temperature. Similar steps are being taken by some of the packers in the case of minced olive relishes, in view of the fact that one death due to the consumption of such a product has been reported. While concerted action to remove ripe olives packed in tin and processed at a low temperature has not been taken by the packers, the fact that spoilage in tin has so consistently resulted in making a "swell" out of the can constitutes a warning to the purchaser which is not often disregarded. There is no reason to anticipate danger from properly packed and processed ripe olives, whether they be packed in tin or glass containers."

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

SURGICAL DISEASES OF CHILDREN. A Modern Treatise on Pediatric Surgery. By Samuel W. Kelley, M.D., LL.D., honorary professor of surgical diseases of children, Medical Department, National University, St. Louis; Pediatrist and Orthopedist, St. Luke's Hospital, Cleveland; formerly professor of diseases of children, Cleveland College of Physicians and Surgeons, Medical Department, Ohio Wesleyan University.[1]

The author argues that there should be children's surgeons as well as children's physicians. In this volume he takes up pediatrics, orthopedics, and general surgery as it applies to children. He pays particular attention to malformations, principally congenital, the surgical conditions which occur mostly in children, and the factors which modify surgical procedure in patients of tender years. Medical treatment is mentioned in those conditions where it is indicated either as curative or as an adjunct to surgical procedure.

The chapters on orthopedics are fairly complete. The chapter on examining children as well as the pre-operative and post-operative care of young surgical patients is well written. As a textbook of modern surgery it can hardly claim pre-eminence. That fibromata change into carcinomata, p. 64, is not in accord with modern pathology. Sapremia is a term which is not as much in vogue as formerly and the author leaves us in doubt as to the exact conditions under which it would occur, p. 125. Finally, it is clear the author does not know just what we understand by the terms "septicemia" and "cellulitis," as he describes the treatment of cellulitis under the heading "septicemia," p. 126 and p. 139, states that "cellulitis" and "Ludwig's Angina" are synonymous, occurring, *e.g.*, as complication of peritonitis and osteomyelitis.

SYPHILIS. A Treatise on Etiology, Pathology, Diagnosis, Prognosis, Prophylaxis and Treatment. By Henry H. Hazen, A.B., M.D., professor of dermatology and syphilology, Medical Department of Georgetown University; professor of dermatology and syphilology, Medical Department of Howard University; member of American Dermatological Association, and National Association for Control of Syphilis.[2]

Any work planned to cover the entire field of syphilis of necessity must include the consideration of certain phases of the pathology practically of every organ in the human body. Such a task obviously can be accomplished only by the cooperation of a large number of experts in special fields. As the result of such collaboration in the past many large, unwieldy, many volumed system and "Handbuch" have been produced, but, in our knowledge, never before a really compact, complete but not complex book like the one before us. In this treatise, after a general discussion of etiology, pathology, and the clinical course of the syphilitic infection, different writers in a number of chapters consider syphilitic manifestations in the respiratory, digestive, genito-urinary, nervous, vascular systems, and in special organs, such as eye, ear, and endocrine glands. The volume closes with chapters dealing with congenital lues, the diagnosis, prognosis, prophylaxis, and treatment of syphilis. Each contributor presents his material in concise form and appends a carefully selected bibliographic list for the convenience of those desiring further information. Most remarkable and praiseworthy for a work of this kind and at the same time a convincing proof of skillful editorship, is the almost total absence of repetition. In spite of the many illustrations, including sixteen colored figures, Hazen was able to compress the contributions of more than a dozen collaborators into the space of over a little more than six hundred pages, representing a most meritorious addition to syphilologic literature.

NEOPLASTIC DISEASES. A Text Book on Tumors. By James Ewing, M.D., Sc.D., professor of pathology at Cornell University Medical College, New York City.[3]

This book is a most painstaking compilation representing the work of many years and bringing into a form for convenient reference a full and reliable account of the etiology, morphology, and the development of tumors.

The general history of tumors and their classification form the thesis of the opening chapters. The subject of malignancy is adequately dealt with in a most thorough analysis of recent experimental work in cancer.

The text is abundantly illustrated. The completeness of the bibliography attests the thoroughness of the work and affords an indication of the trend in this interesting field.

PHYSICAL DIAGNOSIS. By Richard C. Cabot, M.D., professor of medicine in Harvard University, chief of the West Medical Service at the Massachusetts General Hospital.[4]

One always welcomes a new edition of Cabot's justly popular textbook. In the present edition a new section is devoted to hilus tuberculosis, that often unrecognized form of phthisis probably having its origin in infancy or childhood. The physical findings at the onset are often very slight,—some narrowing of the Kroenig zones. The diagnosis must rest upon the constitutional symptoms, pain, and the x-ray findings. Tubercle bacilli are often absent until late. Renewed emphasis is placed on the necessity for operative exploration in cases of suspected interlobar empyema with adequate physical signs. The author has altered his ideas concerning blood pressure in several respects. He acknowledges that simple digital palpation of the artery is entirely unreliable and advises instrumental methods only. He is likewise correct in his changed attitude towards the positive clinical value of the diastelic pressure determinations.

AMERICA'S MOST FAMOUS DESSERT
JELL-O
TRADE-MARK REG. U.S. PAT. OFF.
A MIXTURE
SPECIAL PACKAGE
NET WEIGHT 28 OZS
MAKES FOUR QUARTS
RASPBERRY
PURE FRUIT FLAVOR
VEGETABLE COLOR
This package makes four quarts of Jell-O. Serves forty to fifty persons according to size of portion.
Dissolve the contents of the package in four quarts of boiling water and set in a cold place to harden.
If only part of the contents is to be made up at one time, allow exactly one pint of boiling water for each 3½ ounces (100 grams) of powder.
Further directions of great importance are given on each of the two side panels of this package. Be sure to read them.
THE GENESEE PURE FOOD COMPANY
LE ROY, N.Y.

The Special Size for Hospitals

One gallon instead of one pint of Jell-O is made up from the new Special Package of Jell-O, saving nine-tenths of the time required for opening and emptying the common small size.

This change eliminates the last remaining bit of real work connected with the preparation of Jell-O dishes.

Among the dishes which the nurse likes to prepare are the refreshing and attractive salads of which the foundation is Jell-O. These are made by adding to the Jell-O chopped celery and bits of fruit and nutmeats. They are moulded in teacups or little moulds and each is turned out on a lettuce leaf.

As Jell-O contains sugar and the other ingredients that would have to be added if plain gelatine were used, there is a great saving of time and labor, and the result is always satisfactory. The nurse who uses Jell-O for her dainty dishes is never obliged to depend upon luck.

Jell-O is made in six pure fruit flavors: Strawberry, Raspberry, Lemon, Orange, Cherry, Chocolate.

The new Special Package for hospital use contains enough Jell-O to make four quarts of jelly as against one pint of the regular small size.

AUSTRALASIA.....STERLING & CO.
Modern Chambers, 317 Collins Street, Melbourne.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRITPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

POISONOUS PROTEINS. The Herter Lectures for 1916 Given in the University and Bellevue Medical School, New York. By Victor C. Vaughan, M.D., LL.D., Dean of the University of Michigan Medical School.[5]

This little monograph contains some of the results of Vaughan's extensive investigations of poisonous proteins. General outlines are given for the procedure to obtain poisonous proteins from bacterial and vegetable sources. The reactions resulting from the introduction of these products into the animal organism are described. One chapter is devoted to the discussion of protein fever. The author does not maintain that all the conclusions are correct but that they are supported by his experimental data. The lectures are not only interesting and instructive but they suggest questions for further investigation.

BACTERIOLOGY IN ABSTRACT. By A. B. Wallgren, B.S., M.D., assistant professor of biology, University of Pittsburgh; pathologist to the Pittsburgh Hospital, St. Margaret's Hospital and Columbia Hospital. Author of "Histology in Abstract" and "Pathology in Abstract."[6]

The only conceivable excuse for such a book as this is to meet the requirements of some examination. Nor is the treatment of the subject at all complimentary to the intelligence of the supposed examiners. The "practical" instructions go further than are useful to one who has no need to apply them; they are insufficient to serve as a guide in the laboratory. The author seems to know little and to think less of work done under other than German names. A sentence of the following construction may perhaps contain the key to this: "It is as yet not positive as to the specificity of this organism for whooping cough." The English is weak throughout. The author is under the impression that "media" is a noun in the singular number.

A TEXT BOOK UPON THE PATHOGENIC BACTERIA AND PROTOZOA FOR STUDENTS OF MEDICINE AND PHYSICIANS. By Joseph McFarland, M.D., Sc.D., professor of pathology and bacteriology in the University of Pennsylvania; pathologist to the Philadelphia General Hospital.[7]

This ninth edition of McFarland's text book on Pathogenic Bacteria and Protozoa is even more welcome than previous editions of his work. The book has kept pace with the developments of the subject and there is incorporated in it all of the work up to practically the time the book went to press. The chapters on rat-bite fever and infectious jaundice indicate this. The illustrations are excellent, numerous, and much clearer than in most text books on bacteriology. The subject matter is complete, but is well condensed into the smallest possible amount of space. The arrangement of the book is systematic, both from the point of view of a text book and a book of reference. The table of contents is well arranged and the index is unusually complete and easy of reference. The bibliographic index is especially to be commended, which, together with the bibliographic references given in footnotes, gives the book an unusual value to a student or a laboratory worker. The thoroughness with which the bibliographic references are given, gives McFarland's book the position of being almost unique in this respect among American text books. It is hoped that other authors of text books will imitate this excellent quality. This boek can be recommended as the best elementary reference book known to the reviewer on the subject.

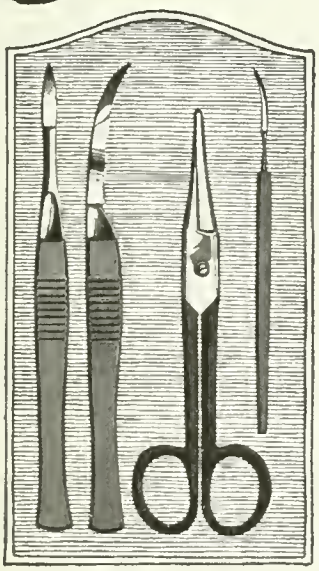
Always ready-

Always Sharp ~ Always Untarnished ~ Always Polished



STELLITE SURGICAL INSTRUMENTS meet in every particular the exacting needs of the profession. Stellite is an alloy of semi-rare metals, containing no iron, and surgical instruments made of it will not rust, tarnish, stain or corrode. They are not affected by sterilizing processes or preparations, including iodine and bichloride of mercury, nor are they affected by heat up to 1800° F.

Instruments made of this beautiful metal are harder than any steel, and will take keener points and edges, yet they may be readily resharpened should the need arise. They will remain sharp much longer than instruments of steel.

STELLITE Surgical Instruments are not only the best obtainable, but are, we believe, the most beautiful made. Surgeons everywhere use and endorse them.

NERVOUS AND MENTAL DISEASES. By Archibald Church, M.D., professor of nervous and mental diseases in the Northwestern University Medical School, Chicago; consulting alienist, Bellevue Hospital; manager of the Craig Colony for Epileptics at Sonyea, N. Y.[8]

It seems almost a useless expenditure of energy to attempt a critical review of such a standard textbook as Church and Peterson has grown to be since it first appeared many years ago. No book can run through so many editions and still be so popular unless it is worthy. This book certainly deserves everything.

RAMBLING RECOLLECTIONS. An autobiography. By A. D. Rockwell, M.D.[9]

If the reader of this book is looking for inspiration which will stir him to action in his chosen field, he will be disappointed. If he is a bit older and the wear of the winter days is beginning to show itself by the longing for the rest in the shade of a summer vacation, he will enjoy this book. As the title indicates, the book is merely a series of interesting recollections of busy life. Stories of the Civil War and the life of the soldier fill many pages; Rockwell's contacts with different men and women of his day fill many more. It is a good book to carry with you on your vacation.

MANUAL OF SURGERY (Rose and Carless). For Students and Practitioners. By Albert Carless, C.B.E., M.B., M.S., Lond., F.R.C.S., Colonel (Temp.), A.M.S.[10]

A certain venerable astronomy professor would say when he wanted to bestow special praise upon some astronomical treatise, "That work, gentlemen, is a veritable mine of information." This is a fitting description of Rose and Carliss, tenth edition, a veritable mine of surgical information. In preparing this edition the lessons taught by the war were analyzed with a view to their applicability to civil life, and, where deemed advisable, were incorporated. Like the former editions, the book is well written, the material carefully chosen, and the subjects freely illustrated. The reader feels throughout the benefit of the author's wide experience and profound surgical judgment.

FOOD INSPECTION AND ANALYSIS. For the Use of Public Analysts, Health Officers, Sanitary Chemists, and Food Economists. By Albert E. Leach, S.B. Revised and enlarged by Andrew L. Winton, Ph.D.[11]

The reviewer of this book believes that the art of feeding can be made the scientifically therapeutic procedure as is the art of giving drugs. One of the most important factors which will improve scientific dietetics is an extension of the knowledge of foods. He will then start off his review of the book by the remark that physicians should be included in the group of food economists for whom the book is written. Chapters are devoted to details of laboratory equipment, to the methods of food analysis, and to the analysis of all kinds of foods. An appendix containing many beautiful photomicrographs of cross-sections of food is not the least interesting part of the book. The book is so thorough, so complete, and, despite its wealth of technical detail, so easily read, that we could wish it to become a part of the library of every hospital and of every physician who has any hopes of intensive and scientific application of food to the needs of his patients.

Flavor as a Means to Adequate Nutrition

Palatability of food induces the partaking of an amount sufficient for proper nutrition.

Hence, flavoring agents are essential constituents of the diet of persons of jaded appetities, especially invalids and convalescents.

SAUER'S
PURE FLAVORING EXTRACTS

stimulate the desire for food to which they are added, so that the maintenance of adequate nutrition is never a matter requiring persuasive measures with the patient.

Various American and European Expositions have awarded seventeen highest awards to Sauer's Extracts for Purity, Strength and Flavor.

Sauer's is the largest selling brand in the United States.

Richmond, Virginia

ALCOHOL AND HEALTH

A summary of the study of the experience of forty-three insurance companies of the effect of alcohol upon health has been presented by Mr. Arthur Hunter, actuary of the New York Life Insurance Company. The study, according to Mr. Hunter, showed conclusively that:

Nothing has been more conclusively proved than that a steady free use of alcoholic beverages, or occasional excess is detrimental to the individual.

Among the men who admitted that they had taken alcohol occasionally to excess in the past, but whose habits were considered satisfactory when they were insured,—*the extra mortality was equivalent to a reduction of over four years in the average life of these men.*

CIVIL SERVICE EXAMINATIONS

The United States Civil Service Commission announces an open competitive examination for reconstruction assistants in physiotherapy and occupational therapy September 7, 1920. Entrance salaries are announced as $600 to $950 a year, with quarters, subsistence, and laundry, and a temporary increase of $20 per month granted by Congress.

The subjects, with weights, are (1) physical ability, 10; (2) education, training, and experience, 90.

The announcement specifies the duties of these positions and the requirements for eligibility to appointment.

Applicants must have completed at least eight grades of common school or equivalent education and have had the experience specified in one of the following groups: (a) At least one year's scholastic experience in teaching or working in one of the trades or occupations listed above under occupational therapy. (b) At least one scholastic year's successful teaching of commercial and academic subjects.

NURSES' INSTITUTES ANNOUNCED

The National Organization for Public Health Nursing is planning a series of summer institutes for public health nurses. The tentative schedule for the season is as follows:

Fish Creek, Door County, Wisconsin....July 1 to 15
Hull House, Chicago, Ill.....July 15 to 29

These institutes are to be planned and conducted on an entirely new idea. The nurses are to alternate study and play. The morning hours and part of the afternoon will be given to class work and round table discussion. The remainder of the day will be given over to recreation.

The Educational Committee of the National Organization for Public Health Nursing is planning the outline of study. There will be lectures and round tables on the following subjects: The principals of public health nursing; public health administration programs; sanitary science; and practical application of sociology to family and community needs in relation to nursing.

These institutes are not to be considered a public health nursing course but are instead a series of formal and informal conferences on subjects of practical interest to nurses engaged in public health nursing.

Admission is limited to graduate, registered nurses who have had at least six months experience in practical field work in public health nursing or nurses with a shorter experience supplemented by a regular course approved by the National Organization for Public Health Nursing. The program fee will be $5 payable at the time of registration, which will he on the opening day of each institute.

Is Plenty of Sleep A Waste of Time?

THE day's work is pressing. Every man has about twice as much on hand as he ought to be asked to do.

Few people sleep long enough, or soundly enough. Many begrudge the time the right kind of sleep requires. Others who do get their full night's sleep fail to be benefited by it. They do not properly relax. Their bed squeaks and rattles. They devote the proper length of time to sleep but, somehow, they are restless, disturbed, sleepless—

As a result, they start the day only half rested, are inefficient and dissatisfied with their work and accomplish little. "Sleep" to them becomes "almost a waste of time."

Nobody can sleep deeply and be fully benefited by their sleep unless he or she is completely relaxed—unless the bed *invites* sleep instead of repelling it.

No bed that rattles and squeaks with every turn of the sleeper can be expected to make "sleep" anything else but "a waste of time."

For over forty years Simmons Company has been making beds and springs that *invite* sleep—

Beds that stand true and staunch; that lock firm at the corners, each part rigid, secure and in perfect alignment; beds that are noiseless, comfortable, sanitary, serviceable, and enduring.

Simmons Beds, "*Built for Sleep*" cost no more than perfect beds ought to cost—no more than anybody who values comfort and health will be fully prepared to pay.

The quiet elegance, simplicity and refinement of their design, their superior construction and the certainty with which they encourage sleep, make them essential to the health, comfort and efficiency of the people.

Special Data and descriptive booklets of Simmons Beds for Hospitals, Schools and Outdoor Recreation Camps, will be mailed promptly on request.

ELECTRO SURGICAL INSTRUMENT COMPANY

Rochester, N. Y.

STATE AND TERRITORIAL HEALTH OFFICERS CONFERENCE

The annual conference of the State and Territorial Health Officers with the United States Public Health Service was held in Washington May 26 and 27. A number of interesting resolutions were adopted, among them being an approval of the standard railway code of sanitation recently issued by a special committee, a recommendation against the creation of duplicate boards as provided in federal bills for maternity care, recommendation for federal supervision for maternity and infant care, and a special recommendation for measures to improve rural health.

PSYCHIATRIC SOCIAL WORKERS WANTED

To aid the United States Public Health Service in a national campaign for volunteers to be trained as psychiatric social workers among the 50,000 World War veterans suffering from nervous and mental diseases, the American Red Cross is offering summer school courses, on a scholarship if necessary. Positions are open in the fall to qualified candidates at salaries ranging from $1,500 to $2,100 a year. Smith College, the New York School for Social Work, and the Chicago School of Civics and Philanthropy provide the courses and will receive Red Cross students.

TUBERCULOSIS RESEARCH FELLOWSHIP

To encourage study of the means for the prevention and cure of tuberculosis, the Hennepin County Tuberculosis Association of Minneapolis, Minn., announces that it has set aside a fund for the support of a tuberculosis research fellowship in the Graduate School of the University of Minnesota. The candidate for the fellowship will be expected to devote himself to research in some problem concerned with the causes, prevention, or cure of tuberculosis. No teaching or other service will be required. The fellowship yields $750 the first year and progressively increasing amounts to be appropriated for the second and third years as conditions warrant. Inquiries and requests for application blanks should be addressed to the Dean of the Graduate College, University of Minnesota, Minneapolis, Minn.

INACCURATE CLINICAL THERMOMETERS

A campaign has been begun by Dr. Frank J. Monaghan, acting commissioner of health, New York City, to drive out of use inaccurate clinical thermometers. Numerous complaints regarding defective thermometers in use by doctors and nurses having been received, an investigation was ordered. As a result of the investigation, it is proposed that the sale and manufacture of clinical thermometers be placed under the jurisdiction of the Health Department. The investigation covered manufacturers and also the thermometers in use by physicians and nurses. While most of the manufacturers are found to be exercising greatest care in testing thermometers, there were some who did not exercise such care. A large number of thermometers were found to be so inaccurate as to constitute a menace to the health of the patient. The report expressed the opinion that if regulations were adopted in New York to prevent the sale of defective clinical thermometers, Federal laws would also be required to prevent the marketing of rejected thermometers elsewhere.

The Cost of Calories

6,221 calories
35 cents

A large package of Quaker Oats contains 6221 calories. It will make 60 dishes. And it costs 5½ cents per 1,000 calories.

On the calory basis, meats, eggs, fish, etc., cost nine or ten times as much.

500 calories
30 cents

One chop costs as much as 12 dishes Quaker Oats. One egg would buy several dishes.

Yet the oat is almost the ideal food. In balance and completeness it's the greatest food that grows.

700 calories
35 cents

A Quaker Oats breakfast means better feeding. And it means a saving which will help buy costlier foods for dinner.

Note how other good foods compare in cost, at this writing, on the calory basis:

Cost per 1,000 calories	
Quaker Oats	5½c
Average Meats	45c
Hen's Eggs	60c
Chicken up to	$1.66

Quaker Oats

Made to make the oat dish doubly delightful. Flaked from queen grains only—just the rich, plump, flavory oats. We get but ten pounds from a bushel, yet it costs no extra price.

The Quaker Oats Company

Chicago

SURGEONS ELECT OFFICERS

At the forty-first annual meeting of the American Surgical Association held in St. Louis May 3 to 5, under the presidency of Dr. George E. Brewer, the following officers were elected: President, Dr. John B. Roberts, Philadelphia; vice-presidents, Drs. Harvey G. Mudd, St. Louis, and James F. Mitchell, Washington, D. C.; secretary, Dr. John H. Gibbon, Philadelphia (reelected); treasurer, Dr. Charles H. Pack, New York City; and recorder, Dr. John H. Jopson, Philadelphia (reelected).

AMERICAN ASSOCIATION OF ANESTHETISTS

At their annual meeting in New Orleans in May the American Association of Anesthetists registered in unmistakable terms their disapproval of the employment as anesthetists of any but men and women licensed to practice medicine or dentistry. They elected the following officers: Dr. Joseph E. Lumbard, New York City, president; Drs. Frank L. Richardson, Boston, and Eleanor C. Seymour, Los Angeles, vice-presidents; and Dr. F. Hoeffer McMechan, Avon Lake, O., secretary-treasurer.

RESEARCH IN MENTAL DISEASES

The New York Neurological Society has undertaken to foster research in nervous and mental diseases through an association recently formed which purposes the investigation by a properly constituted commission of subjects assigned three years in advance of their annual meetings, only one subject to be discussed at a meeting. The first meeting will be held in New York in December, 1920. Dr. Walter Timme, New York City, is chairman of the Organization Committee. Dr. Frederick Tilney, New York City, has charge of the Committee on Arrangements for the first annual meeting.

THE NATIONAL RESEARCH COUNCIL

The National Research Council, a cooperative organization for the application of scientific knowledge for the benefit of national welfare, has elected the following officers for the year beginning June 1, 1920: Chairman, H. A. Bumstead, professor of physics and director of the Sloane physical laboratory, Yale University; first vice-chairman, C. D. Walcott, president of the National Academy of Sciences and secretary of the Smithsonian Institution; second vice-chairman, Gano Dunn, president of the J. G. White Engineering Corporation, New York; third vice-chairman, R. A. Millikan, professor of physics, University of Chicago; permanent secretary, Vernon Kellogg, professor of biology, Stanford University; treasurer, F. L. Ransome, treasurer of the National Academy of Sciences.

The Council was organized in 1916 under the auspices of the National Academy of Sciences to mobilize the scientific resources of America for work on war problems, and reorganized in 1918 by an executive order of the President on a permanent peace-time basis. Although cooperating with various government scientific bureaus it is not controlled or supported by the government. It has recently received an endowment of $5,000,000 from the Carnegie Corporation, part of which is to be expended for the erection of a suitable building in Washington for the joint use of the Council and the National Academy of Sciences. Other gifts have been made to it for the carrying out of specific scientific researches under its direction.

Gradwohl Laboratories

Chicago—7 W. Madison St.
St. Louis—927 N. Grand Ave.

are especially equipped to satisfy the needs of

Industrial Surgeons

By reason of well equipped laboratories and skilled workers we are prepared to handle all your problems in this line.

Every Wassermann is supplemented by a Hecht Gradwohl Blood Test which adds ***thirty per cent*** to the column of correct positives.

Our blood chemical methods are accepted everywhere as standard.

Sanitary Water Analyses

Medicolegal Problems of all kinds.

Consult us freely. Literature and containers Free on Demand.

Let us assist in the great work of INDUSTRIAL MEDICINE.

Cleans **COFFEE POTS** and **URNS** quickly and thoroughly, making them as good as new.

Cleans **URN SACKS** thoroughly, taking out all the Coffee odors.

DO NOT USE SOAP when cleaning metals with the solvent. The ideal way to clean metal surfaces, and avoid injury, as well as save labor, is to use a cleaner that will loosen the dirt and grease without harm to the hands.

ARISTON MAGIC SOLVENT will meet every requirement for perfect cleaning with the least effort and positive assurance of no injury. One spoonful to pail of water is plenty for general use.

A 5-pound carton will last a long time.

Send us a dollar and we will ship you a 5-lb. carton. It is not packed in larger size, as the solvent should be used sparingly.

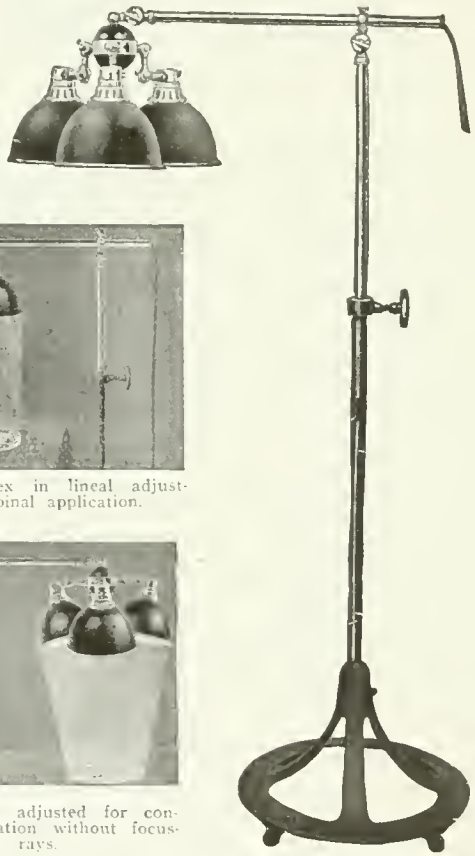
CALUMET TEA & COFFEE COMPANY

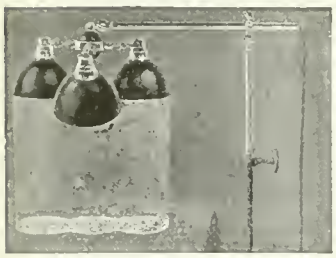
409-411 W. Huron St., Chicago, Ill.

"Dealers Direct with You"

Thermolite
LIGHT AND HEAT INFUSER

TO RELIEVE pain and speed recovery of workmen in every industrial and public health station the THERMOLITE is a most essential apparatus. Radiant light and heat delivered in parallel rays have deep penetration and bring quick relief from pain, reduce inflammation and promote healing quicker and better than drugs or local applications in many conditions encountered daily by industrial physicians.





Showing Triplex in lineal adjustment for spinal application.

Showing Triplex adjusted for concentrated application without focusing rays.

Most therapeutic lamps designed for industrial purposes have but a single large reflector, with a high powered lamp in the center. This does not permit much adjustment in the intensity or illuminating area in front of the reflector, whereas with the THERMOLITE (Triplex Type) the light can be projected in a curved or straight line, concentrated or diffused, to any degree, and all without focusing the rays. It can be attached to any electric light socket.

THERMOLITE is supplied in two forms, the Triplex for hospital clinics and office use, and Simplex (single lamp with or without stand) for home use.

Send for prices and free book "Phototherapy."

H. G. McFaddin & Co.

39 Warren St., New York City

PREVALENCE OF SPEECH DEFECTS

That speech defects are more widely prevalent than is generally appreciated is the opinion of the National Society for the Study and Correction of Speech Disorders as expressed in a recent official statement that 1,500,000 cases in the United States are a conservative estimate, the cases probably actually numbering around three million in all. The Society has 839 members, practically all of whom are actively correcting speech disorders and pushing ing the mental hygiene and mental development of those found defective.

THE JEWS AN URBAN RACE

The total Jewish population of the United States is estimated to be 3,300,000, of which number one and one-half million are in the city of New York, according to the Twelfth Annual Report, just issued, of the American Jewish Committee. Of the total Jewish population 75 per cent is concentrated in ten cities, namely, New York, Chicago, Philadelphia, Cleveland, Boston, Baltimore, St. Louis, Pittsburgh, Newark, and Detroit. There is also a direct relationship between the general population of cities and the Jewish population, the Jewish population rising as the general population is greater. In the nine largest cities, excluding New York, which is exceptional, the percentage of the Jewish to the general population is about 10 per cent; in the sixty-two next largest cities, those having a population of 100,000 or over, the average is a little less than 4.5 per cent; in cities between 50,000 and 100,000 the average ratio is 3 per cent.

THE SCIENTIFIC USE OF STATISTICS

An editorial in the *Public Health Nurse* for May, 1920, discusses the scientific use of statistics from the standpoint of the public health nurse and argues for the wider use of statistics in the promotion of health. To quote part of the editorial:

To many public health nurses the keeping of statistics is an irksome matter, of very small importance compared with their actual nursing work. To spend on the writing of records time which might be devoted to the help of the sick seems to them unreasonable. And so it certainly is, unless the records so kept are such that they may be made of real use. This is a point in regard to which each nurse should surely satisfy herself, by studying the why and wherefore of the records she keeps and ascertaining to what uses they are put or are capable of being put. To relieve suffering and help to restore the sick to health is greatly worth while; but so to make use of the history of sickness that it may be utilized to prevent further suffering is also of much value. And who has a better opportunity than the public health nurse for "the comprehensive study of *the facts as they are* in daily life and environment and not only as they are in the laboratory"?

In the same issue of the magazine an excellent article appears on "Florence Nightingale as a Statistician," by Dr. Edwin W. Kopf. Referring to the article in question the editorial goes on to state:

Florence Nightingale saw in the careful collection, presentation, and, above all, scientific *use* of statistics the foundation of sound health measures, anticipating in this as in so many other ways, the conception of our own day, and giving one more demonstration of the truth that a right principle, once apprehended, is equally applicable in all ages.

Professorship in Anesthesia

The first professorship in anesthesia to be created in the United States has been accorded Dr. S. Griffith Davis recently by the University of Maryland.

ACUTE SUMMER DIARRHOEA

The doctor found John Bignell, 5½ months old, apparently suffering from intestinal tuberculosis; periodical sickness and diarrhoea prevailed; unable to assimilate food.

Improvement immediately followed the use of VIROL in small doses, mixed with whey; child out of danger in one month. Second photo taken six months after first.

DIET IN INFANTILE DIARRHOEA

To each half pint of barley water or rice water add a half teaspoonful of VIROL and give one or two ounces of the mixture every two hours.

Virol is composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine: refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars: 50c, $1.00 and $2.00

Liberal samples of VIROL and interesting literature will be mailed to physicians on request.

The addition of VIROL under suitable conditions enormously stimulates the phagocytic powers of the white blood cells. These sturdily attack the microbial invaders, and by diminishing the intestinal flora cut off the production of toxins at their source, with a consequent reduction of the catarrhal condition of the mucous membrane.

As the glandular secretions become more normal they again exercise their inhibitory effects upon the flora, and digestion and assimilation are again established.

Virol

More than 2,000 Hospitals and Infant Welfare Societies use VIROL in Great Britain

REPORT ON DRUG ADDICTION

A recent report of the experience of the New York City Narcotic Clinic, prepared by S. Dana Hubbard, M.D., of the Bureau of Public Health Education, has been issued as a reprint. This report gives the different points of view on the subject of drug addiction. The report points out significantly that "the problem of drug addiction is somewhat to be compared with village gossip—but few know the actual facts—and it is extremely interesting to find how many peculiar and extravagant opinions are expressed regarding this mystery. This is very applicable to the facts regarding drug habits." The conclusions of the report are briefly:

Number of addicts.—The estimate of 1 per cent of our population addicted to the use of narcotic drug indulgence as a habit—addiction—is very likely greatly exaggerated.

Class of addicts.—Instead of many persons being made narrotic drug users incident to improper prescribing by careless doctors, it is found that drug addiction spreads like a pestilence through association. In a study of more than 7,500 addicts in this city exemptions requested for persons ill of some malady numbered less than 250.

Physical condition of addicts.—Instead of drug addicts being of that thin, emaciated, starved, hollow-eyed, cadaverous type of individual, very many appear physically normal.

Feeble-mindedness of addicts.—Very many of these unfortunates are easily determined as belonging to this group in one of its several degrees. Some are, however, of the constitutionally inferior type and many of these are of the underworld stripe. The mental condition of addicts adds impetus to the opinion that more recognition must be given in our schools to the boy or girl of the mentally inferior type so that by special attention and training—oftentimes individual—many may be prevented from the acquirement of such a vicious habit.

Duration of habit.—From our experience, few seem to continue the habit for a very long period. The vast majority of these cases seem to be under ten years and there are comparatively few longer than this period.

Acquirement of habit.—This appears to vary with localities. Our experience points in the great preponderance of instances to bad and vicious associates, 69 per cent from their own statements. Raising the morale of our public assemblies for the young and making programs in our shops and factories may materially aid in preventing this reprehensible practice.

Efforts to prevent and avoid mental and physical fatigue in industry with a careful regard for opportunities for acquirements of this habit by the industrially employed is strongly indicated.

Results of habit.—The practices of drug addicts to meet the demands of their depraved appetites causes financial embarrassment, and to meet these desires the addicts become immoral and anti-social. When in need of the drug or over-stimulated from indulgence, all moral influence and self-control are lost. These individuals either in need of the drug or under its stimulating influence are a distinct menace to society. They will commit the most revolting of crimes in cold blood. It is from the ranks of these that petty thieves are recruited.

Treatment.—Drug addiction is not a mysterious disease. From a purely scientific point of view it would be interesting to have more light on the problem of tolerance, but on therapeutic indications and possibilities there is but little difference of opinion. Drug addicts, under careful medical and supervisory nursing, present no pathological condition—only a disturbed or prevented functioning. The action of internal organs are inhibited or functionally disturbed; but, when these influences are removed and normal action permitted this derangement quickly disappears.

It is our opinion that any form of cure can take an addict off his drug provided this is done promptly. This was done at Riverside Hospital, in three to five days, without discomfort to the patient. From information obtained from the large number of addicts who have come to our clinic, most of whom have taken various methods of

The Modern Idea in
Artificial Feeding of Infants

Mead's Dextri-Maltose
is prepared
in Three Forms
No. 1. With Sodium Chloride, 2%.
(For average baby.)
No. 2. Unsalted or plain.
(For the physician who wishes to add larger amounts of salt.)
No. 3. With Potassium Carbonate, 2%.
(For the constipated baby.)

Mead's Dry Malt Soup Stock
is prepared especially for the marasmic type of baby. Such cases generally thrive astonishingly well on Dry Malt Soup (a mixture of cow's milk, maltose, dextrin, wheat flour and potassium carbonate).

Human milk is the best baby food and cow's milk, intelligently and properly modified, is the best available substitute.

Proper modification involves the addition of sugar and food salts which Mead's Dextri-Maltose supplies in forms suited to different feeding conditions.

Individual infants differ so greatly in food requirements and food tolerance that no standard feeding mixture can be employed, but each case must be fed according to its own needs.

These needs can only be determined by a physician. *Hence our adoption of*

THE MEAD JOHNSON POLICY
Mead's Dextri-Maltose is advertised only to the Medical Profession. No feeding directions accompany trade packages. Information regarding its use reaches the mother only by written instructions from her doctor on his own private prescription blank.

Write us for interesting literature explaining our policy and our methods. Our key for preparing individual formulas will interest you.

MEAD JOHNSON & CO., 304 St. Joseph Avenue, Evansville, Ind.

Physical Conditioning

So many patients, especially women, lack the initiative to follow general advice regarding exercises, dietary, and personal hygiene. Physicians acquainted with my work are constantly referring these cases to me for physical and mental "conditioning."

A woman can often inspire her sex *to be* and *to do* and *hold her to this inspiration* by regular correspondence as men cannot.

Every pupil's requirements are studied individually, and each is directed according to her needs and her strength.

This cooperative work with the medical profession is giving results highly gratifying to both physicians and patients.

I shall be glad to assist you with patients who need conditioning through exercise, diet, breathing, correct poise, relaxation, reduction of flesh, or building of flesh.

Boon to Industry

50 to 80% of American young women suffer from dysmenorrhea. There is scarcely a factory, store, office, school or home that is not interfered with on account of young women being seriously affected fourteen times yearly. Every physician in charge of the health of women industrial workers recognizes the great economic loss to industry by absenteeism and reduced production. Painful menstruation is the most frequent cause.

Benzyl Benzoate, a harmless, non-toxic, non-narcotic, antispasmodic relieves over 80% of all cases of dysmenorrhea, proving a great economic asset and greatly reducing human suffering.

Since the commercial Benzyl Benzoate is unfit for therapeutic use on account of producing gastric irritation, it is important to specify the product of The American Chemical Laboratories to insure a chemically pure preparation.

We Commend Bénol—our standardized emulsion, as the best form for administering this valuable drug.

Brochure and sample sent upon request.

AMERICAN CHEMICAL LABORATORIES
PHILADELPHIA, U.S.A.

The Standard for Twenty Years

Carnation Milk, because of its uniformly high quality and absolute purity, has found wide favor throughout the country.

It is just cows' milk from which a part of the natural water content has been removed by evaporation, hermetically sealed in new containers and then sterilized.

The use of Carnation Milk in the diet kitchen is steadily increasing due to the fact that its convenience, economy and purity are appreciated.

our cure, it may be concluded that all methods of withdrawal are equally efficacious and only differ in regard to the comfort of the addict while taking the cure. Aftercare is always essential.

Treatment of the narcotic drug addict by private physcians prescribing and druggists dispensing, while the individual is going about, is wrong. The giving of a narcotic drug into the possession of an addict for self-administration should be forbidden. Until this is done by law all honorable physicians should aid in stopping this vicious practice. The case of drug addiction that can be cured by ambulatory treatment is the rare exception, and so unusual as to make one think it impossible. Physicians generally are of the opinion that ambulatory treatment is not good practice, and few doctors use this form of treating addicts, it is believed that those so doing must be either ignorant of proper methods, or do so in bad faith.

Harrison Act enforcement.—Our study of this problem in this city indicates most positively the necessity for the general and uniform enforcement of the statutes. There will be no panic or falling in the streets, or robbing of drug stores or crowding of physician's offices by the addicts affected. If they cannot obtain a supply, they will reform, and it is certain that not a fatality will be recorded.

General conclusion.—The work of reclaiming the narcotic drug addict, in this vicinity at least,—judging from those we have seen and helped,—is more than worth while.

COURSE IN PUBLIC MENTAL HEALTH

A special course in Public Mental Health is offered by the Division of the Criminologist of the Illinois Department of Public Welfare in cooperation with the Chicago School of Civics and Philanthropy in Chicago June 21 to December 18, 1920. The work will be divided into two main periods, June 21 to September 7, during which time the work will consist of alternating class room instruction and field work. The second period, September 7 to December 18, will be devoted to field work in one or more of the state institutions. Thesis work may be included with the necessary supervision of statistical work.

HEALTH OF MILLINERY WORKERS

A report of conditions affecting health in the millinery industry was recently made by Dr. S. Dana Hubbard and Christine R. Kefauver of the Division of Industrial Hygiene, Department of Health, City of New York. This report of thirty-five pages summarizes briefly the health hazards in the industries related to the manufacture of millinery. Among other hazardous branches of the trade is that of artificial flower making, which, the Report states, carries the greatest menace to the health of the worker. This industry requires the use of numerous chemicals, many dangerous machines, and also materials which affect the health of workers.

INTERNATIONAL MEDICAL CONFERENCE

Dr. Simon Flexner, director of the Rockefeller Institute, represented America at the first formal meeting of the Medical Advisory Board of the League of Red Cross Societies.

Representatives from other countries who attended the international conference in July are: Belgium, Professor Brodet; Denmark, Professor Madsen; France, Professor Roux, Professor Albert Calmette, and Dr. Leon Bernard; Great Britain, General Lyle Cummins, Sir Walter Fletcher, and Sir George Newman; Italy, Professor Bastianella and Dr. Castellani; Japan, Dr. Kinnostke Miura; South America, Dr. Chagas.

LEGAL CONTROL OF GLANDULAR PRODUCTS

At a session of the Section of Medicine of the New York State Medical Society during the recent meeting held in New York City, Dr. S. W. Bandler suggested the wisdom of legal control of the sale of glandular products for life extension or other purposes. He urged the appointment of a committee of fourteen physicians to take the initiative in the matter of the prevention, by legislation, of the sale of such products by druggists without a physician's prescription.

REGULATION OF INDUSTRIAL NURSING

It is reported that the State Board of Health of Rhode Island has sent a letter to all industrial plants in the state employing industrial nurses defining the limitations of duties of such nurses. They state that the reason for the action was that the Board's attention had been called to certain instances where manufacturers require nurses in their establishments to do certain things that infringe on the medical practice laws of the state.

ILLUMINATION AND PRODUCTION

Production is handicapped to a striking degree by poor illumination in factories, according to a statement by Ward Harrison, illuminating engineer, Cleveland, O., in an address before the Taylor Society at Rochester on "The Necessity for Standards in the Relation Between Illumination and Output." Mr. Harrison declared that most industries are saving one dollar by not improving illumination and losing ten dollars through decreased production. Study has proved, he says, that night shifts are inefficient partly because of inadequate lighting.

Y. W. C. A. HOLDS NURSES' COUNCIL

The Young Women's Christian Association, in connection with its regular summer camp conference, is including a Nurses' Council at Lake Okoboji, Iowa, from August 7 to 14, 1920. Student nurses, hospital nurses, and public health nurses are eligible as members of this conference.

A competent athletic director and a swimming teacher and life guard will take care of games, boating, swimming, hiking, giving instruction as well as directing sports. Picnics, parties and pageants will be the part of the program that each group will organize for themselves.

For information address Miss Winnifred Wygal, 425 Northwestern National Life Building, Minneapolis, Minn.

Ohio Public Health Organization

A new association was organized at Columbus, O., May 12, to be known as the Ohio Public Health Association, and the following officers were elected. President, Dr. Chester B. Bliss, M.D., Sandusky; vice-presidents, Dr. lucian G. Locke, Portsmouth, and Mrs. W. C. Marshall, Selma; secretary, Dr. Robert G. Patterson, Columbus; and treasurer, Mr. Theodore S. Hunter, Columbus.

Endowment for Psychiatric Clinic

The founder of the Phipps Psychiatric Clinic, Henry Phipps, New York, has made a gift of $100,000 as a nucleus of a permanent endowment for the Clinic. Heretofore the Clinic has been supported by a maintenance fund provided for a period of ten years by Mr. Phipps.

GENERAL WILLIAM C. GORGAS

IN THE passing of General William C. Gorgas the United States has lost one of its greatest men, one who, because of the immense benefits his labors conferred upon mankind, deserves a lasting memory and the highest honor. Born in Mobile, Ala., in 1854, the son of a West Point graduate, he received his early education at the University of the South, Sewanee, Tenn., of which institution his father became president. He came North in the seventies to pursue his medical education at Bellevue Medical College. Following his course in the hospital there he received a doctor's commission as lieutenant in the Army and was sent to Fort Brown, Tex., at which post his conflict with yellow fever aroused in him an interest in the malady which later on was to be practically eliminated by his efforts.

His remarkable talent as an executive sanitarian was first revealed during the Spanish War. He accompanied the Army in the Santiago expedition and was put in charge of the yellow fever wards of the Las Animas Hospital in Havana. The discovery of the mosquito as the intermediate host in the transmission of this disease was utilized by General Gorgas in his effectual campaign in "cleaning up" the Havana capital.

This work brought him general attention and in 1905, when it became necessary to make healthful the area surrounding the workers on the Panama Canal, he was chosen by the Government to eradicate the twin scourges, malaria and yellow fever, and the success of his work made possible the notable engineering achievement of General Goethals. The views of General Gorgas as to so-called ineradicable tropical disease are expressed in his own words thus:

"I dare to predict that after a lapse of a period, let us say equal to that which now separates the year 1909 from the Norman conquest of England, localities in the tropics will be the centers of as powerful and as cultured a white civilization as that which now exists in the temperate zone."

There was nothing spectacular in his conquest of tropical diseases in the Panama region. In silent laboratories with chemical formulae, in stagnant pools and dismal swamps with ash can, larvacides, and fumigants, the war was waged against yellow fever until the death rate of the Isthmus from this disease was reduced in five years from eight thousand to a paltry nineteen.

At the instance of the British Government he was sent in 1913 to investigate conditions in the Rand mines of South Africa, where epidemics of pneumonia were carrying off thousands of Kaffirs. On his return in 1914, having served in Panama as a Colonel and as Assistant Surgeon General, he was promoted to the rank of Surgeon General, and later was made a Major General. In 1915 also he became a permanent director of the International Health Board of the Rockefeller Institute, and his last great work against yellow fever in its stronghold, Guayaquil, in the tropics under the auspices of that body, was a complete success.

General Gorgas served as head of the Medical Corps during the recent war and achieved for our Army the distinction of a mortality rate of six-tenths of one per cent, lower than that on the basis of which claim had been made that the Japanese army was the model of hygiene in all military history.

Among the many honors conferred upon General Gorgas may be mentioned the gold medal of the American Museum of Safety, the Mary Kingsley Medal from the Liverpool School of Tropical

Gen. William C. Gorgas.

Medicine, and the Presidency of the American Medical Association in 1908. He was a member of several other medical organizations and a United States delegate to the first Pan-American Medical Congress in Santiago, Chile, in 1908. During his recent visit to Milbank Hospital, London, King George of England bestowed upon General Gorgas the insignia of Knight Commander of the Order of St. Michael and St. George, in recognition of his services to Great Britain and the rest of the world.

Public Health physicians and sanitarians everywhere will feel humble in the presence of such achievements and such high objectives, but will receive a new incentive to carry on the work achieved at such personal cost, and will realize that nothing shall stand in the way of improvement when science is linked with such service as this.

REFORM FROM WITHIN OR WITHOUT?

AS a people we are inclined to place too great a reliance on the general rightness of things and to proceed without thought or question on the assumption that evolution toward a better social order is predetermined, and that time will take care of and eliminate any faults or false starts that may be charged to the present.

It is true that when reforms are reviewed with a proper perspective the manner in which apparently conflicting tendencies fall into harmony points to the planning of human affairs by an architectonic mind and leads to the conclusion that laws of being we are not even aware of are constantly operative and, no matter how erratic the ways of individual action or how false individual judgment, there is never at any time any great deviation one way or the other.

This, however, is not to be construed as a release from the dictum that "right conduct is thought-out conduct," and certainly the scientific mind is bound to base its prerogative upon observed facts and to found its attitudes upon reason rather than upon selfish or emotional reactions. Evasions, substitutions, or denial of facts have no place in the scientist's code.

All of this is pertinent to issues now before the medical profession. Discussions regarding the reorganization of medicine range from apathy or scorning aloofness on the one side to acrimonious and unreasoning opposition on the other. Opposition to change is of course not without its element of self-interest on the part of those who would suffer financial loss from any system of universal supervision of health matters, and there is a measure of justifiable caution in efforts to prevent a possible exploitation of medicine with its consequent lowering of standards. The time is upon us, however, when all thinking members of the medical profession must recognize that change is imminent, indeed that it is imperative. The public is at last interested in its welfare and must be guided to self-help. Science is not for the esoteric, but must be made to serve popular needs and demands.

Health facts as revealed by the Army draft and by such extensive surveys as have in the past few years been made in Ohio, Illinois, Pennsylvania, Massachusetts, and, more recently, in New York, constitute a basis for constructive thought in this direction. Numerous expedients in the way of group practice, and community and hospital health centers now being tried out should be measured most carefully as to their efficacy and adaptability.

To such an end we present on another page of this issue of MODERN MEDICINE the annual discourse of Dr. Hugh Cabot before the Massachusetts Medical Society June 9, 1920, as an example of the constructive criticism which tends to keep the initiative of reform in the hands of those best fitted by training and habit of mind to fill this difficult rôle of reformers from within. S.P.M.

COMPULSORY HEALTH INSURANCE, STATE MEDICINE, OR WHAT?*

By HUGH CABOT, M.D., F.A.C.S., Ann Arbor, Mich.

IT has perhaps been a weakness of the medical profession that it has not sufficiently exerted its great potential influence in directing or influencing the changes in the relation of medical practice and medical custom to the community. We have on the whole been too apt to regard such things as other people's business and have held the view that the care and management of the sick constituted our whole relation to the community. But it must now be perfectly clear that with the variety of suggested cures for the real or imaginary evils which are believed to surround the practice of medicine we must think clearly and act together and wisely if we are to prevent various developments which we believe to be unsuited to the requirements. Change is in the air. A demand for a closer relation between the public and its health agencies is widespread and proper. Democracy cannot hope to satisfy the claims of its admirers unless it can show success in protecting itself against the diseases of body and mind with which it is threatened.

PUBLIC HEALTH OBJECTIVES

The problem of the complete care of community health becomes a social problem. The means of achieving this service is through a well thought out plan based upon data obtained through experimental health centers, the authority back of such health administration being an enlightened public opinion that knows what it wants and insists upon getting it.

Given these conditions, selfish class opposition on the one side would be as ineffectual as lack of cooperation because of ignorance on the other, and the greatest good for the greatest number would eventually be achieved.

Society Gives Derelicts Best Care

The present demand for change of some kind has its source in a variety of conditions. Perhaps the most fundamental is a dissatisfaction with private charity as a method of caring for the ills of those who are unable to pay for satisfactory care. The system by which we have provided almost the best skill that the community can afford for the care of the paupers and the derelicts of society has been outgrown. The self-respecting though impecunious citizen demands and has a right to expect that he can obtain care at least equal to the average of medical knowledge without being driven into debt or bankruptcy. Undoubtedly the almost universal adoption of compensation for industrial accidents has started people thinking and they properly inquire why, if they are entitled to protection from accident chargeable against the business in which they are concerned, they are not entitled to insurance against illness chargeable to the same source. Compulsory health insurance was long ago instituted in Germany and not so long ago the so-called "panel system" of health insurance was put into effect in England. Many people, and particularly those dissatisfied with present conditions, have heard of these alleged panaceas and believe that they know about them, though they are far more apt to hear of their excellencies than of their deficiencies; and, finally the widespread demand for protection against illness is part and parcel of the general restlessness or unsettled conditions and the very human though utterly hopeless desire to get something for nothing.

Compulsory Health Insurance

It does not seem essential to enter into any lengthy dissertation here on the much discussed and widely advocated system of health insurance. We are familiar with the claims made by enthusiastic advocates and most of us have come to an opinion in regard to the propriety of such an arrangement. But in order that no doubt may exist as to my own opinion I will briefly note what seem to me overwhelming objections to the system.

In the first place, as at present advocated in the various bills which are before the many state legislatures of the country, it does not, as far as I am aware, even propose to insure or to care for the illness of the majority of the population. It is not suggested that any of the systems advocated will have any effect in the prevention of disease or in the diminution of its incidence, and yet the casual minded are rather led to believe that in some mysterious fashion such a result will accrue. It is not proposed, as far as I am aware, to apply this system to all members of the community who are or believe themselves to be financially unable to obtain satisfactory medical attention. It is pro-

*The Annual Discourse, delivered before the Massachusetts Medical Society, June 9, 1920. Reprinted by courtesy of Dr. Cabot and the Boston Medical and Surgical Journal.

posed to apply it only to workers in industrial concerns where it can be charged against the cost of the business and thus become a tax upon the community which may be borne without being unduly burdensome. Furthermore, as far as I can judge from the experiments in other countries—and the experiments in England appear very enlightening for us—the whole tendency of this method is to promote second rate methods of practice. The fees which the physicians doing this work can be allowed to charge are of necessity low, and this tends to attract chiefly physicians of average or less than average capacity.

A more serious objection is that it tends to promote what may be called the method of "pill peddling" in medical practice. It tends to perpetuate the methods of one or two generations ago under which the physician made numerous visits but, being unequipped with the machinery for precise diagnosis, as a rule contented himself with treating symptoms and trusting to the healing powers of Nature. The last twenty years has seen a great effort to get away from this inefficient method, yet now we are asked to saddle ourselves with a system which is as sure as anything to restore to respectability this fast disappearing practice. As part and parcel of this same difficulty, health insurance does not assume to provide and probably will in practice discourage the tendency to send patients to a hospital where they can be studied with the best results to themselves and the least expenditure of unnecessary time and exertion by the physician. For these reasons it appears to me certain to promote a method of practice unlikely to promote health or to shorten the loss of time from disease.

Another prime consideration is its effect upon the medical profession who give their lives to it. It has been sometimes argued that this and various other methods would tend to make medicine an unattractive calling. From the point of view of the medical practitioner this is a valid objection. From the point of the community, on the other hand, the medical profession can have no rights which the public is bound to respect to its own disadvantage. If it could be shown, which I think it cannot, that this or some other system would promote health, the medical profession would have no case at the bar of public opinion even though it were sacrificed to the method. But it appears to me quite clear that this method of practice will not only fail as a panacea for the health of the community but will debase the practice of medicine so that all parties will be worse off.

Obviously under some system comparable to the "panel system" in England, a premium is placed upon the number of visits or calls that a given practitioner can make. From this it follows that it is clearly to his financial interest to see the least serious cases and to visit those who live in his immediate vicinity. Obviously, to care for the seriously ill is likely to consume time wholly out of proportion to the fee received, and sick patients and those who live at a distance are likely to suffer. It might further be suggested that this system tends to promote the sort of snap diagnosis which flourished in the earlier days of the out-patient clinics of the metropolitan hospitals when they were understaffed and overworked and from which we have been trying to escape ever since.

For these and various other reasons it seem to me clear that compulsory health insurance will inevitably work to the disadvantage of the community and to the very grave disadvantage of the medical profession; but clearly it will not do for us to assume a negative attitude. If we are unwise enough to sit complacently by, it is wholly probable that some system will be put in force which we believe entirely unsound. As evidence of this probability may be taken the situation in England, where the organized medical profession opposed the system suggested by Mr. Lloyd George and to a considerable extent refused to assist him in working out some satisfactory method. As a result he went ahead on his own responsibility and there resulted the "panel system," which now bids fair to be most useful as a warning to the unwary.

State Medicine a Threat, Not a Plan

The phrase state medicine is commonly used to convey some ill defined arrangement by which the state shall become the responsible source of medical practice. It is probably often intended to convey the idea that all physicians should become salaried officers of the state. In this form it is probably rarely used as a constructive suggestion but is intended like the Democratic Party in the days following the Civil War to serve as a threat rather than as a plan. There is, I believe, no sound reason for believing that medicine could thrive in such an atmosphere. At best such a service would be comparable to that now existing in the medical establishments of armies and navies the world over, and in this form it is notorious that lack of inspiration and degeneration more or less inevitably follow.

But if we are inclined to object to it on the ground that it will injure the personnel of medicine there will not be lacking those who oppose it on other grounds. It is certainly to be opposed by those who advocated what they pleased to call

"medical freedom" and who yearly appear before our legislatures in opposition to bills proposed in the hope of improving the condition of the public health. It will also be opposed, and not without reason, by those whose business it is to determine how such a method should be financed. If these officers of the state are to be paid sufficiently large salaries to command the services of really first class men, the bill must be little short of staggering, and, coupled with the steady tendency to saddle the state with many expenses which in the past have been thought unnecessary or of private concern, will probably not commend itself to the average legislature.

State Responsibility for Health

In this form, therefore, I think we need not consider it in the light of a present possibility. If, on the other hand, we understand this somewhat loose phrase to mean progressive assumption on the part of the state of responsibility for health questions, such a situation now exists. More and more the state has been assuming responsibility for certain phases of medicine, chiefly in the field of preventive medicine, and enormous improvements have been made in comparatively recent times. To progress along this line there can be no valid objection and it is not inconceivable that the time may come when we shall be willing to advise the state to enter more and more into the field of curative as well as of preventive medicine. If, construing the phrase still more widely, we understand by state medicine the assumption by communities of responsibility for the care of the sick, we then approach a phase of the question which is inviting and one in which there is much evidence that activity looking toward definite change is widespread.

We rightly believe that our knowledge of the complicated business of looking after the sick entitles us to be heard. I believe there is no reasonable doubt that we shall be heard if we have a constructive plan, and equally little doubt that if we should unwisely confine our efforts to obstruction that we shall receive, if possible, less consideration than we deserve. It is, therefore, with the hope of stimulating discussion and thought rather than with any overweening confidence that I have a wholly satisfactory plan to propose that I desire to invite your attention to a possible line of development which appears to me at least worth considering.

Essentials of Satisfactory Method

Whatever method we adopt must aim to insure to every member of the community satisfactory medical treatment without requiring him to accept charity or go into debt. It must allow a reasonable freedom of choice or, if choice is to be restricted, must guarantee a high grade of medical skill. It must reasonably distribute the cost so that it shall not be unnecessarily burdensome and, finally, it must not interfere with the proper development of the science and art of medicine. We might, perhaps, lay more stress upon this latter point and insist that any system, to be satisfactory, must show evidence of actually promoting the development of medicine.

In attempting to suggest a method of improving present conditions it is only proper to recognize that various experiments are being tried and with varying though considerable degrees of success.

Industrial Medicine

This phrase is often loosely used to cover the medical establishments which have been set up by employers for the purpose of caring for their employees. For many years these establishments have been growing and have now been carried to a high degree of efficiency. There can be no manner of doubt that many of the great industrial corporations now provide for their employees an amount of medical care which closely approaches the ideal. They have wisely provided well trained physicians properly paid, and have organized their work on a system or variety of systems which would go far to solve the problem if it were satisfactory to what one might call the insured. But it is commonly true that the employees for one reason or another dislike this method. It is alleged that they suspect the evidence of paternalism. It is alleged that they object to this limitation of their freedom of choice, and it is alleged that the corporations use the method to their own advantage.

Though these allegations may appear shadowy and unsubstantial, there is probably some basis for the widespread belief that the problem will not be solved in this way. To my mind the greatest objection to this method is that it is a solution carried out privately, but charged against the community in the heightened cost of production, and yet the community has no voice in its management. On the other hand, there is doubt that these establishments have served and are serving a very useful purpose. For the time being, at least, they give time for the orderly discussion and consideration of the problem and they provide an immense amount of what one might call experimental evidence on the methods of managing industrial accidents, diseases, and conditions arising within industry. Whatever method may be finally adopted, we shall owe a considerable debt to these pioneers in this method of caring for the sick upon a large scale.

The phrase "group medicine" has of late years come into vogue to cover what almost amounts to partnerships between the specialties of medicine. These groups are a serious attempt to solve the problem which we are discussing and have undoubtedly promoted efficiency in the diagnosis and treatment of disease. The chief objection to regarding them as the best method of solving the problem is that they are only incidentally constructed for the benefit of the patient. This benefit consists more largely in increased efficiency than in increased expense. It is certainly true that in many of these medical groups the financial benefit of the group rather than of the patient has been the commanding consideration.

The Community Health Center

By whatever method we may finally decide to care for the health of the community the fundamental proposition upon which it is based must be that the public health is a public concern. From this it follows that the soundest method will be that which is based upon community consciousness. For this reason I look to some development in the now rather vague field covered by the phrase "community center" for the solution of the problem.

A great variety of possible developments may be here included. In its simplest form a community may provide itself with a director of health whose business it shall be to coordinate existing agencies, encourage cooperation, discourage duplication, and promote efficiency. In this form it is already in operation in various parts of the country. But it may be doubted whether without more means at his disposal such a director will obtain results at all commensurate with the effort expended. A slight advancement from this plan is to provide such a director with a staff of physicians whose business it shall be to keep in touch with the medical activities of the community and go further than he himself could go along the line of influencing medical practice by suggestion and publicity. But, again, this arrangement falls short of providing sufficient power and does not enable the director and his staff to exert the authority of public opinion which must at the last analysis be the ultimate authority.

One of the clearest signs of the times is the tendency of medical practice to group itself about hospitals, and there can be no doubt that in the future of medicine the hospital will play an increasingly important part. For this reason it has appeared to me wisest in any scheme looking to the provision of care for all members of the community to start with the hospital as a basis and create what might be called the hospital center, whose function it should be not only to provide care within its wards but to radiate medicine in the community at large. The possibility appears to me attractive, but to be successful it must have a far broader conception than the municipal hospitals with which we are all familiar. It must take its authority from an educated public opinion which knows, broadly speaking, what it wants and is prepared to employ experts to obtain it. Undoubtedly such a method can be worked out most easily in comparatively small communities where there is a small city with a large area of surrounding country ultimately dependent upon the city for medical service. Under such conditions one might well conceive that some such machinery as the following would work with considerable satisfaction.

Such a community might construct and own a hospital with sufficient capacity to take care of something more than the average number of sick, not only in the city but in the surrounding district which it must serve. It is perhaps not necessary that this should be calculated to provide accommodations for those who ordinarily avail themselves of private physicians or private hospitals; but, on the other hand, if such a hospital is to be a perfect health center, it should be constructed so as to provide everything which that community wants for the care of its bodily ills. Obviously in communities of large population, it may be wise to construct several such hospitals as there is undoubtedly a working unit in hospital construction beyond which efficiency of operation is sacrificed. But for a moment let us assume that a hospital of no gigantic dimensions will fill the bill, and let us further assume that it is planned to provide accommodations for all sorts and conditions of men.

Group Control of Hospital

In charge of this hospital must be a group, perhaps called a board, who properly represent the wishes of the community, and I believe that this board should serve without pay, so that the only motive for service on the board will be an abiding desire to serve the community. This board must provide itself with a general manager who must, I believe, be a physician, in order that he may be reasonably familiar with the problems with which the board must deal. Such general manager or director must have large powers in executing the policy of the board.

The board must next provide itself with a staff capable of covering the entire field of medicine and medical research, and this staff must be at the service of the community. The problems involved in the selection of such a staff are ob-

viously considerable, particularly if such a hospital is to be started in a community already supplied with a sufficient number though perhaps not sufficient variety of capable physicians. Clearly this staff must be of more than average skill and equally clearly their skill and qualifications must be beyond reasonable doubt and, therefore, must be determined by some authority having no interest beyond the determination of the facts. In order to avoid difficulties the board would probably be well advised to avail itself of the advice of directors of great medical centers who are constantly engaged in the training of experts in every field of medicine. In order to obtain and retain the services of such a staff, proper salaries must be paid, and it may well appear that the provision of such a sum will bear heavily upon the community. This difficulty may, I think, in part be solved by allowing this staff to practise in the ordinary sense of the word and to collect fees from such patients as are able to pay. As the staff, when under this arrangement, would consist of well trained, capable specialists, it would certainly follow that their services would be in considerable demand in the community and that their income from this source would go far to make up the guaranteed salaries which they would be assured of by the board.

From this it would result that the community through the board would pay only the balances and might conceivably not have to pay at all.

The Patients Who Are Eligible

Some difficulty will undoubtedly arise in determining what patients are entitled to free care and treatment, what patients should be partly free, and what patients can defray their own financial obligations. This difficulty, however, is at least much diminished if we assume that this is in fact a community hospital. It is not difficult if proper machinery be provided to ascertain what are the living conditions of any individual and what is his income relative to his obligations. If we cannot assume that the community really wants to promote its own health and is willing to take any reasonable steps in order to do so, then of course this method will fail; but so will any other method, and on this line of argument the whole proposition becomes insoluble.

Open vs. Closed Hospitals

The medical profession will of course be vitally interested in the question of whether this community hospital is to be what is called "open" or "closed." It is, I think, generally admitted that if one has regard only for a high grade of efficient medical practice the closed hospital is likely to give the best results. On the other hand, it is practically a contradiction of terms to refer to a closed hospital as a community hospital. A closed hospital at once denies the freedom of choice which is generally admitted as essential if it is to command the confidence and support of the community. Physicians who are barred, though in good standing, will obviously not send their patients to a closed hospital unless they be compelled to by fear of disaster either to the patient or to themselves. It cannot, I think, be successfully contended that a closed hospital can satisfactorily serve the whole community and, therefore, some sacrifice of efficiency is necessary in the interest of the community operation. The answer to this dilemma perhaps lies in a combination of the two methods. The staff provided by the community must obviously look after those patients who are unable to pay and also such other patients as desire their services. Beyond this, the hospital might well be opened to all reputable physicians with the proviso that the board shall have the power to exclude any physician whose work does not match up to a reasonable standard of excellence.

But such a hospital will not have performed its functions if it stops here. It is growing more and more difficult to provide satisfactory medical care for the small villages and scattered populations of the outlying districts. I am firmly of the opinion that provision for such care is entirely within the function of the community hospital and that unless it serves this purpose it will fail to radiate medicine and, consequently, fail of its purpose. The work now done by isolated physicians attempting to cover a large area of territory could well be taken over by the hospital, whose business it would be to establish throughout the surrounding country small centers provided with a young physician and one or more nurses. These people would be constantly in touch with the hospital staff, thus obtaining advice, consultation, and comfort. While they should be integral parts of the hospital staff, they should be movable rather than fixed and this service should be regarded as a part of the training of the younger men who intend to fit themselves for the practice of medicine in its broadest sense. This line of development seems to me particularly attractive. It would enable such a community hospital to offer a variety of opportunities, particularly to the younger medical men whose capacities are unknown and who might in this way, better than in any other, have an opportunity to survey the broad field of medical practice. The same proposition would hold true as regards the nurses associated with smaller centers. They would see medi-

cine in its relation to people as is not now possible in the hospital training schools. As a result they would not only be better equipped for whatever branch of nursing practice they ultimately espouse, but they would have larger opportunities of surveying the field and thereby learning their own capacity.

I submit this rough sketch of possible medical development for your consideration. It is obviously incomplete, open to objection, and its pathway strewn with thorns. I hope that you will find in it the merit of a conscientious attempt at a constructive program based upon the assumption that the community really desires to have its health properly supervised and its illness properly treated. Any scheme is subject to this consideration and, though it may fairly be doubted whether the community consciousness throughout the country is sufficiently developed and crystallized to know its own wants, it is possible that in various places such experiments may be tried and may prove helpful to a final solution.

FERRY BOAT A PREVENTORIUM

Ferry boats, which have been put out of running by the building of new tubes, have been transformed by the Health Department of New York City into "Preventoriums" or open-air schools for children with tuberculous tendencies.

The boats are anchored at the piers and have been divided into schoolrooms, play rooms, kitchens, and dining rooms. There are shower baths and dental clinics, and doctors and nurses are always in attendance.

Regular hours are apportioned for study and the usual subjects are taught, together with sewing and some of the other manual arts. All work is done in the open air unless the inclemency of the weather makes this impossible. Desks—just as in a real school—are used and all books and necessary material are furnished.

Rest is one of the corrective measures employed and the shaded decks form an ideal place for the sun baths which are regularly insisted upon. The big "comfy" deck chairs are never empty during this period.

Another important part of the building-up process is the serving of regular meals properly proportioned, as in many cases the lack of proper nourishment is the main contributing cause of the physical disability of these student patients. The meals are supplemented by lunches of bread and milk "between times" and the periods devoted to them are always eagerly looked forward to.

In the dental clinics the teeth are given special attention, and at regular periods physical examinations are made. The enterprise results in bringing back vigor to wasted bodies and in making useful citizens of some who might have become merely human derelicts.

Air and sunshine, in effect life savers, are now furnished in abundance to the kiddies of the poorer sections of New York and Brooklyn as the result of municipal progressiveness and the present trend toward the prevention as well as the cure of disease.

The children are taken from the dark, smoky environment and transported to the river where all the long golden days are spent in doing the things which will rid them of whatever physical disability they may have, or strengthen them against possible contagion.

SOCIOLOGICAL PHASES OF THE TUBERCULOSIS PROBLEM IN CHILDREN

By A. LEVINSON, Chicago, Ill.

EVERYONE interested in tuberculosis is aware of the fact that in the main tuberculosis is a social problem. Certain phases of this problem are to be emphasized in regard to the prevention and treatment of the disease in children. From this angle the first phase concerns itself with the question of what to do with children whose parents are tuberculous, and who themselves may not as yet have contracted the disease. The second phase brings up the question of what to do with children who are already infected, whether the process be active or latent.

HEALTH OUR BIRTHRIGHT

More and more it is coming to be appreciated that the curative arts cannot be limited to the study of disease, for corrective measures must be made to include the causative factors.

Especially is this true of tuberculosis in children, which is too often the result of environment and social conditions, the remedy often involving social methods that are subversive and difficult to apply.

A health campaign which gives the child a place in the sun must provide for a training in health habits that will prevent many a handicap in maturer years.

Contact Tuberculosis Among Children

What is to be done with children of tuberculous parents? Are they to be allowed to live with or should they be separated from their parents? If separation is advised, is the parent to be removed from the house, in case only one parent is infected, or should the children be removed from home? If the children must be sent away, should they be sent to a sanatorium or should they be boarded out? Important as is the care of tuberculous children, the protection of children who come in contact with tuberculous adults is of still greater importance, and in the proper handling of contact cases many a case of tuberculosis may be prevented.

Whether or not tuberculosis is hereditary, it must be conceded that the greatest number of cases among children are caused by contact with adults after birth. At present, most people who study tuberculosis clinically and pathologically believe with Ghon and Albrecht that the route of infection in most cases is respiratory, and that the primary focus is usually lodged in the lungs. Children acquire the infection from direct contact with active tuberculosis in adults.

An investigation of a series of 106 cases of tuberculosis in children treated in the tuberculosis clinic for children at the Michael Reese Dispensary demonstrates once more the relation between tuberculosis in the children and that in other members of the family (Table 1). I believe that contact cases should be dealt with according to the conditions of the tuberculous parents—as to whether they are open—raising sputum—or closed cases—and according to the hygienic conditions of the homes. The first rule in dealing with this question is that children must not come in contact with an open case of tuberculosis, whether existing in the father, mother or other member of the family. The tuberculous members of the family must be removed from the house, in which case the child may remain home, provided the other members of the family are non-tuberculous.

When the parent or other member of the family is a closed case, the removal of the child from the house depends on whether the father or the mother is the offending party. If the father is tuberculous and the mother is not, the child should remain with the mother all during childhood, and the father should be removed to an institution, for no one can predict when the father may become an open case. In the presence of tuberculosis in the mother, even if the condition is inactive, the child should preferably be removed from home.

Where to send contact tuberculosis children constitutes a very serious question. They do not belong in a sanatorium for tuberculous patients, as they may contract the disease there if they are not already infected; yet one does not like to place them in an institution together with normal children. As to private homes, people are prejudiced against children of tuberculous parents, especially if there are children in the family.

The best answer that can be given to this problem would seem to be the provision of a special home, where children who have come in contact with tuberculous parents may be sent. There they

can be under the supervision of physicians and nurses, they can be examined frequently to ascertain whether or not they have been infected with tuberculosis and, if so, whether or not the infection can be localized. This would require frequent physical examinations, x-ray and flouroscopic inspection, and special tuberculin tests. Such cases should be kept at the special home until puberty, at the time when the glandular type of the disease changes into the pulmonary type. This will also help the children bridge over the critical period of their lives by giving them special attention, such as rest, diet, and general hygiene. This would have the added advantage of providing means to gain statistical information on this very important type of cases.

Whether or not contact cases are treated in a special home, they should be given special attention and should preferably be treated as tuberculous cases without the children being made

TABLE I.

THE INCIDENCE OF TUBERCULOSIS IN FAMILIES IN WHICH ONE OR MORE OF THE CHILDREN SHOWED A POSITIVE VON PIRQUET TEST.

Total No. Cases Investigated.	Father			Mother			Others in Family		
	Open	Closed	Non-tuberculous	Open	Closed	Non-tuberculous	Open	Closed	Non-tuberculous
106	39	35	29	10	32	64		69	29

aware of the fact. The various tuberculin tests should be employed frequently to ascertain whether or not they have acquired the disease and, if so, at what age. They should be examined at frequent intervals and should be given sunshine, fresh air, and good food.

Care for Infected Children

Before discussing the sociologic phases of the treatment of tuberculous children, it is necessary to define the term, tuberculous children; for as yet there has been no uniformity of opinion as to what constitutes tuberculosis in childhood and what are the main diagnostic features of the disease in childhood. In order to get a working basis I would divide tuberculosis in childhood into (1) acute and miliary tuberculosis, (2) active chronic tuberculosis, and (3) latent glandular tuberculosis.

Miliary tuberculosis, as is well known, consists of the presence of miliary tubercules in all the vital organs of the body; such as the lungs, heart, liver, spleen, and kidneys, usually terminating as a tuberculous meningitis. This form of tuberculosis is of more frequent occurrence in infants, but may be present in children and even in young adults, although in the latter it is very infrequent.

In active chronic tuberculosis the infection is localized in certain structures of the body. It may manifest itself in the form of a pleural effusion, in involvement of bones or joints or of glandular structure. The mesenteric and the cervical glands are the two chains of glands most frequently involved, the first giving rise to tuberculosis peritonitis and the second to cervical adenitis.

Latent glandular tuberculosis is the form of tuberculosis most frequently seen in children, the tracheobronchial glands being the ones usually affected. The children look pale and anemic and occasionally present symptoms due to tracheobronchial pressure, such as brassy cough, expiratory whoop, and hoarseness. Often, however, no symptoms manifest themselves. The x-ray often shows an enlargement of the glands. Percussion often gives hilus dullness, and auscultation usually shows a positive D'Espine sign—whispered bronchophony—and Eustace Smith's sign, venous hum over aortic region. Most significant of all, the child reacts to tuberculin.

After an experience of several years I do not hesitate to make the statement that the only diagnostic sign for the presence of latent tuberculosis in children which very seldom fails is the tuberculin reaction. The other symptoms and signs may or may not be present; in other words, when a child reacts to tuberculin I consider him tubercular even though he show few or no chest findings. On the other hand, if the child does not react the tuberculin, and I am reasonably certain that the tuberculin is active, I consider that child non-tuberculous.

The Weight of Clinical Signs

It should be made clear that importance of clinical signs and symptoms is not to be minimized in the diagnosis of tuberculosis of children. I even consider general appearance, long eyelashes, distended veins over the chest, and winged scapula as indicative of the presence of tuberculosis. The final diagnosis, however, should not be made without the presence of positive tuberculin test, bearing in mind that the reaction does not necessarily mean an active process and that it does not localize the infection, but that it does indicate the presence of a tuberculous infection, active or latent, somewhere in the body.

Miliary tuberculosis and active glandular tuberculosis, as a rule, do not present any sociologic problems as both conditions call for hospitalization. Miliary tuberculosis is fatal in a short period. Active glandular tuberculosis must either be operated upon, in which case the patient must be sent to the hospital, or may be treated with heliotherapy or various inunctions and fresh air,

and these cases as a rule belong to a sanatorium. The great sociologic problem comes up in connection with latent glandular tuberculosis, namely, with children who give a positive tuberculin reaction but who may or may not be sick. The question comes up as to whether these children should be sent to a sanatorium or whether they should be treated at home; as to whether they should come in contact with other children or should be separated; as to whether they should attend school or should be kept out of school. While every child must be individualized, there are certain generalizations of thought that may be formulated in connection with the problem of tuberculous children.

Acquired Attitude a Factor

The treatment of latent tuberculosis in children depends entirely on status of the home, and on the condition of the rest of the members of the family. If the home conditions are good, that is, if there is plenty of sunshine and air in the house; if the child gets good nourishing food, and has enough sleeping space; and, above all, if there are no "open" cases in the family, the child can be treated at home; in fact, it is best for the child to stay at home, for psychological reasons. Children who are sent to a tuberculosis sanatorium acquire a certain mental attitude that makes invalids out of them mentally. More than once have I heard children who have been for five or six months in a sanatorium speak of "Con," as abbreviation for consumption, and "San" for sanatorium; of hemorrhages and of cavities, things that the child should not become acquainted with. It should be our aim to keep close watch on the child's entire physical condition without letting him feel it, without letting him concentrate on his condition.

A child with latent tuberculosis may and should go to school. An open air school is the ideal place for an infected child. If, however, there is no such school in the neighborhood, no harm results either to the child himself nor to other children in permitting him to attend an ordinary school; for at best latent cases are "closed" and thus their presence does not endanger other children.

Rest is one of the principal requirements in the supervision of a tuberculous child, no matter how latent the process may be. Home conditions, and especially home discipline, will therefore play a great rôle in determining the question whether or not the child is to remain at home or is to be sent to a sanatorium. If the mother is unable to discipline the child, to make it rest at the prescribed hours and to take proper nourishment, it may become necessary to remove the child from the home surroundings. In that event a sanatorium may be the only place available, although I usually prefer a rest haven for this type of children, so as to avoid the mental effect of a sanatorium.

If the home conditions are bad, with lack of sunshine, lack of air, or lack of cleanliness on the part of the parents; if the child is unable to get good nourishment because of the poor circumstances of the parents; if the child has no sleeping accommodations, and is obliged to sleep in one bed with another person; or, what is most important, if there is an open case in the family which for some reason or other cannot be removed from the house, the child should be sent to a sanatorium. The results from sanatorium treatment in this type of cases are usually very gratifying. The only drawback in many of these cases is the fact that after several months of sanatorium treatment the child usually has to come back to the same home conditions because of which he was removed, thus undoing all the good that has been accomplished.

The question of special sanatoriums for children is one that should arouse a great deal of interest amongst physicians and social workers. A tuberculous child is much happier in the company of another child than he is in the company of an adult. If no special sanatorium for children is obtainable, a special department for children in a tuberculosis sanatorium is very desirable. It also goes without saying that children with latent tuberculosis who are placed in a sanatorium should be taught the principles of primary avocation the same as normal children. The whole matter may be summarized by saying that the treatment of tuberculosis in children, that is, latent tuberculosis, depends in a great measure upon the social history of the others of the family.

SCHOOLS UTILIZE PLAY INSTINCT

Recreation in Oakland, Calif., makes playgrounds of the school yards, community houses of the school buildings, and the educational work of the school dovetails with the activities of the playground in such a way that where the school teacher leaves off the playground director takes up the work. Wherever possible, supervision is extended to adults as well as children and the program is so constituted that it meets the needs of rural schools with poorly equipped grounds as well as those of the more pretentious city grounds, as it requires a minimum of equipment. The ethical value of such an arrangement is fully demonstrated in Oakland, says *The American City*, and economy has been served as well. Under this plan physical education became a part of the school curriculum, and credits were given for the work in athletics. Team games were resolved into their elementary movements, which exercises replaced the more formal gymnastics of the turnverein type. These exercises became a continuation of the study of physiology and hygiene and were later put into effect on the playgrounds in actual play.

THE ARMY MEDICAL MUSEUM AND THE MEDICAL PROFESSION

By CHARLES F. CRAIG, A.M., M.D., Colonel, Medical Corps, United States Army, Curator, Washington, D. C.

IT IS believed by the author that only a very small minority of the medical profession are acquainted with the fact that in the city of Washington there is available to the medical profession of the United States and other countries one of the greatest collections of pathological and other material, illustrating the etiology, pathology, and methods of prophylaxis of disease and injuries, in the world. This collection is deposited in what is known as the Army Medical Museum, an institution belonging to the War Department and under the control of the Surgeon General of the army. We believe that a short description of this museum and what it offers to the medical profession of this country is of timely interest. The historical data given in this contribution are drawn from a history of the United States Army Medical Museum compiled by Dr. D. S. Lamb, who for more than fifty-five years has been connected with the institution, a greater portion of the time as pathologist, and through whose faithful and enthusiastic labors the greater portion of the collection contributed prior to the recent world war has been prepared, classified, and placed on exhibition.

The Army Medical Museum and Library are housed in Washington and afford a wealth of material and service.

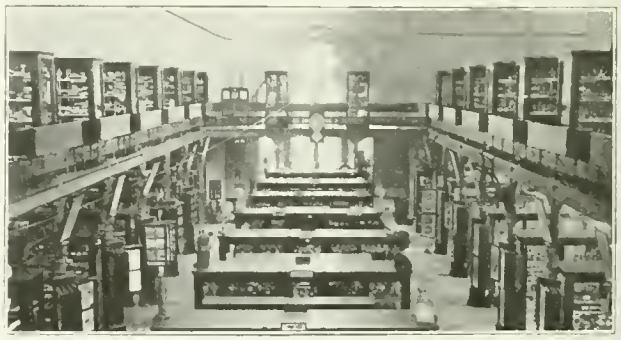
Advanced Medical Science

The Army Medical Museum was established August 1, 1862, by Surgeon General William A. Hammond, United States Army. Primarily its object was to collect and preserve specimens illustrating wounds and diseases causing death and disability in the Army in order that by their study methods could be discovered to reduce suffering and mortality. It gradually became evident that the collection should be extended to include all pathological conditions due both to disease and injury, sanitary models, models of equipment used in the Medical Department of the Army, and models of normal anatomy and disease lesions which could be illustrated in this manner.

The collection of specimens for the Museum was begun shortly after it was established by the surgeons in the Union Army and within a short time enough specimens had been contributed to render the collection one of the most valuable in existence at that time. As early as 1870, Berenger-Feraud stated,[1] "that the United States had done as much in the matter of an anatomical-pathological museum in five years as had been done in all of Europe in a century."

In the same year Saint George Mivart stated:[2]

> The Army Medical Museum contains a series of excellently numbered preparations of great professional interest, remarkable chiefly for its profuse exhibition of the effects of shot, shell, and other implements of war on the human frame. The material for this Museum was chiefly collected during the American Civil War. It may well be said that the Americans are a wonderful people. There are few other nations which would have been capable of so utilizing the results of a protracted internecine war as to make them available in after years toward the advancement of medical science and alleviation of human pain.



This view of the main museum hall shows the convenience of arrangement and the immediate availability of materials.

At that time the collections of the Museum consisted very largely of material obtained from battlefields of the Civil War, but gradually civilian physicians began to contribute specimens, and a very large amount of the material now present in the Museum has come from civilian sources.

1. Gaz. d. hôp., 1870, xliii, 293.
2. Nature, 1870, p. 290.

In 1876 Dr. Meusel, in a review of the catalogue issued by the Museum shortly before this date, said:[3]

The Museum, in view of its aim and origin, is very rich on those chapters which are of specific interest to the military physician. The art and manner with which the material was collected gives us a high opinion of our colleagues, who in the midst of the bustle of war, have brought it together scientifically. It gives us also a high opinion of the organization of the care of the American Army, if we recall how many conditions must be fulfilled in order to give enough time and physicians to prepare after a battle so many careful specimens, as, *e. g.*, the big list of mortal wounds. They lost no time in preparing specimens of interest and instruction to the observer.

In the autumn of 1874, John E. Erickson, after visiting the United States and the Museum, gave a lecture at the University College Hospital, London, in which he stated,[4]

There is one museum which is so unique, so admirably arranged, and so interesting, that I must direct your attention to it for a few minutes. It is the Museum of the Army Medical Department at Washington. This magnificent collection illustrating not only every possible variety of gunshot and arrow injury, but also those diseases which are more fatal than the bullet to an army in field or in camp, has, under the able superintendence of Surgeon General Barnes and Dr. Otis Woodward, been most admirably arranged and catalogued.

From the quotations given it is evident that very shortly after its establishment the Army Medical Museum became noted as a center for pathological research and for its valuable collection illustrating disease and injury. The collections have gradually grown in size and value until at the outbreak of the world war the Museum contained approximately 48,000 specimens, of which approximately 14,000 were specimens of pathological material, 1,300 anatomical dissections and models, 13,000 slides of microscopical sections, more than 15,000 photographs and negatives, and several thousand miscellaneous specimens.

The Collection Grows

Immediately upon the outbreak of the world war it was recognized that the opportunity for securing valuable material illustrating the effects of disease and wounds upon human tissues would be almost unlimited and should be utilized to the greatest extent, and the Surgeon General promptly issued a circular that such material be collected for the Army Medical Museum. A Museum unit for service with the American Expeditionary Forces in France was authorized and dispatched at the earliest opportunity, and the army hospitals in this country were circularized with a view to obtaining pathological and histological material illustrating the lesions of the various diseases occurring in camp life. As a result of these activities of the Medical Department, the Army Medical Museum has a great deal more than doubled the collection that it possessed at the beginning of the war. At the present time the collection numbers more than one hundred thousand specimens, of which a large percentage illustrate pathological conditions. In the comparatively short time that the United States was engaged in this war, the Medical Department of the Army collected and contributed to the Army Medical Museum a larger amount of material than was collected by the Germans during the entire four years in which they were actively engaged in hostilities, and enough to fill a building twice as large as the present Museum if properly prepared and exhibited. All of this material will be available to the general medical profession of this and other countries for study and research and, when classified and prepared for exhibition, will undoubtedly form the most valuable collection of pathological specimens in any museum in the world.

The building at present occupied by the Army Medical Museum and which it shares with the Library of the Surgeon General's Office, is situated at Seventh and B Streets, S. W., and was erected by Act of Congress and finished in 1887, at a cost of $200,000. In addition to the Museum collection there is housed in this building the hundreds of thousands of volumes of the Surgeon General's Library, one of the greatest medical libraries in existence. The building is now totally inadequate in size and it is hoped that in the near future a new Museum building will be erected in which the large amount of material which has been accumulated can be properly classified and exhibited.

From an administrative standpoint the Army Medical Museum is divided into seven departments, as follows: (1) Department of Pathology and Accessions; (2) Department of Still Photography; (3) Department of Moving Pictures; (4) Department of Anatomical and Wax Models; (5) Department of Veterinary Medicine; (6) Department of Anatomical Art; (7) Department of Entomology. In order to understand the scope of the work, it will be necessary to consider each department separately.

Department of Pathology and Accessions

This department has charge of collecting and preparing for the Museum specimens of pathological and other material illustrating the diseases of the soldier and the effects of wounds by various missiles upon the human body, the accessioning of all specimens received by the Museum, and the preparation of all specimens for exhibition purpose. In addition this department has charge of

3. Cor.-Bl. d. Alg. Aerztl. Vereins v. Thuringen, 1876, v. 81.
4. Lancet, London, 1874, ii, 720.

the filing of all records, including protocols of autopsies, for future reference and scientific study. Each specimen, as it is received, is given an accession number and briefly described upon the catalogue card which is filed for future reference, and this file also contains the autopsy protocol, clinical history, photographs, and other data relating to each case.

Modern methods of warfare have resulted in additions to our knowledge of pathology and diseases heretofore unknown have been described. Many specimens have been collected illustrating these additions to medical knowledge and they are being prepared as rapidly as possible for research and instruction purposes. The material is dissected and displayed in such a way as to show not only the wound or pathological lesion in question, but so as to suggest to the physician or surgeon the best means of treatment. Special methods are employed to insure permanency and retention of natural color, so that the preparations will remain a reliable record of the conditions illustrated.

Many thousand gross specimens and histological slides have been received from camps and hospitals both in this country and abroad, and these cover remarkably well the most important diseases observed during the war and war wounds and injuries. There have also been received many hundred specimens illustrating general pathology. This material is being prepared as rapidly as the limited personnel on duty at the Museum permits. Every gross specimen is photographed before being permanently mounted and indexed for future reference and study. In addition photomicrographs are made of slides of particular interest illustrating pathological lesions or animal parasites.

Diseases of the respiratory tract have furnished the largest number of specimens. The influenza-pneumonia series which is being prepared and

A specimen case illustrating war wounds which shows the method of mounting specimens for exhibition purposes.

which now numbers about forty examples of the most striking types, will amount to several hundred specimens when completed and will furnish one of the most valuable collections illustrating the types of pneumonia following influenza in existence. In addition to the gross specimens a wealth of microscopic and pathological material relating to them has been prepared and is being rapidly made available for teaching and research, through the preparation of photomicrographs and lantern slides.

Unique and Valuable Collection

War wounds are represented by amputated extremities and form a large and valuable collection. Most of these specimens show secondary changes due to infection with anaërobic organisms. These specimens are being prepared by sections and dissections in such a way as to display to best advantage the bone lesions and the rela-

tion of the infection to the conditions present. The method of exhibiting these specimens shows to the best possible advantage the damage produced in tissues by modern high explosives, while the colors which have been preserved in the tissue show the differences in the appearance of normal and gas gangrene muscle which is so valuable to the surgeon. There has been enough material of this character collected to make this series extend into many hundreds and even at this early date there have been prepared over ten cases illustrating heart traumatisms.

The tuberculosis series is very large and has been added to greatly during the war. A special selected group of specimens from the United States Army Hospital at Fort Bayard, N. M., has been prepared and exhibited for study. This group consists of approximately one hundred specimens showing practically all types of lesion produced by this disease.

The Museum collection contains many hundred specimens of brains, illustrating all the ordinary lesions observed in this organ and many of the rare conditions produced by disease or injury. Only a small portion of the total material has been prepared for research and exhibition, but when this work has been done the collection will undoubtedly be one of the largest and most valuable in existence.

In May, 1896, the American Dental Association adopted a resolution recognizing the Museum as the national museum of the dental profession in the United States and recommended that all dental collections be deposited there. This has resulted in the accumulation of one of the most valuable collections of dental material in the world, consisting of casts, photographs, specimens of normal and morbid dentition, diseases of the maxillae and oral cavity, photographs and casts of surgical operations, new instruments, and specimens of mechanical work. Most of these specimens are accompanied by descriptions and histories of cases and furnish a vast amount of material of the greatest service to the dental profession.

Besides the collections mentioned, the Army Medical Museum contains one of the greatest, if not the greatest, collections in existence of material illustrating the effect of gunshot wounds upon the bony tissues. This collection was made by surgeons at the time of the Civil War and illustrates the effects of missiles used at that time. In addition to this collection there is an immense collection of fractures due to accident, gunshot wounds, swords and sabers, arrows and tomahawks, and a few by bayonets. While it was impossible to collect anywhere near the material during this war that was collected during the Civil War showing the effects of gunshot wounds, enough material has been collected and will be placed upon exhibition to show the effect of modern missiles both from rifles and larger ordnance, as well as the effects of high explosives and shrapnel.

In addition to these special collections, the Museum has scores of specimens illustrating infectious diseases, chronic diseases of the viscera and blood vessels, malformations and monstrosities, and animal and vegetable parasites. Most of this material is accompanied by excellent clinical, pathological, and other records, rendering it of particular value for research purposes.

From April 7, 1917, to April 7, 1920, more than 22,000 specimens have been accessioned in the Pathological Department, together with more than 21,000 protocols of autopsies. As stated, the pathological specimens consist of material collected both in this country and in France. The latter specimens illustrate well the peculiar diseases associated with trench life and the effect of gunshot and other wounds upon the body. A valuable collection of material showing the effects of the poisonous gases used by the Germans was collected and is now being studied by experts. The pathological collections at present in the Museum offer an almost inexhaustible field for study and research, and owing to the fact that many duplicates have been received, it will make possible the loan of specimens to educational institutions and the exchange with other museums of various conditions not readily obtainable. As soon as it can be done it is intended to place at the disposal of the physicians of the country such excess pathological material as the Museum may possess, and it is hoped in this way that it will fulfill its function not only as a place for the preservation and exhibition of pathological material, but will also assist in the general medical education of the country.

The presence of medical officers in the Army in distant countries who are constantly contributing material to this Museum insures many lesions being represented which are not available to the same degree in civil institutions. This is especially true of tropical diseases, and it is hoped that in time the collection illustrating these diseases will prove of great value to the profession of the United States.

In addition to the preparation and preservation of specimens illustrating disease and injury the Department of Pathology has charge of the accessioning and arranging of all other contributed material. At the present time the Museum possesses a large collection of models illustrating

sanitary apparatus used in the field and in posts; models of apparatus used in the prophylaxis and the treatment of diseases of the soldier; ordnance materials; and miscellaneous specimens of general professional and public interest. It is planned in the near future to remove from the main hall practically all pathological specimens and replace them by models illustrating the methods of prevention and treatment of disease, ordnance and equipment, and other material of general interest not only to the medical officer and practitioner but to the public.

Department of Still Photography

Prior to the recent war, a photographic department was maintained at the Army Medical Museum and very valuable contributions have been made by it to the science of medicine. The first photomicrographs taken in this country were made at the Army Medical Museum by Dr. Gray, and it is doubtful if they have ever been exceeded in accuracy and beauty. A very large number of photographs and negatives illustrating pathological lesions was collected prior to the war and filed with histories and protocols, but the Department of Still Photography was greatly enlarged immediately after the United States entered the war and has accomplished a mass of very valuable work since that time. The photographic section of the Museum unit which was sent to France collected many thousand negatives and prints illustrating the activities of the Medical Department in the field. This department does the photographic work required for the various divisions of the Surgeon General's Office and the Army Medical School, including the making of negatives of copies or prints, enlargements, lantern slides, photostats, and photomicrographs. As already mentioned, a photograph is now being made of every pathological accession received at the Museum and this photograph, together with

Nor is microscopic change alone noted. The pathological exhibits record the gross changes which mark the progress of disease.

Unlimited opportunity for study is afforded by the exhibits of anatomical models.

a photomicrograph, in suitable cases, will be filed with the history of the accession, thus increasing its value for study and research purposes.

This department is also charged with the filing and indexing of the photographs taken by the Medical Department and the Signal Corps photographers during the recent war illustrating various forms of medical activity both in this country and in France. These collections, when suitably arranged, will be available to the services : large by means of copies of prints and lantern slides. Many thousands of x-ray negatives have also been received from the large military hospitals in this country and in France and are continually being received as hospitals are closed. These, when classified and indexed, will form an immense and most valuable collection illustrating almost every condition that can be diagnosed by means of the x-ray. Aside from x-ray negatives, it is believed that there will be a collection of from fifty to seventy-five thousand negatives of photographs of medical activities taken during and since the war, the vast majority of which will be of the utmost value for instruction purposes and in research work.

Department of Moving Pictures

Some months after the declaration of war a moving picture department was established at the Museum as part of the unit known as the Instruction Laboratory, the latter being a field organization attached to the Museum. This department was established for the purpose of producing moving pictures which would illustrate methods of treating disease and wounds, field operations, sanitary procedures, and other activities of the Medical Department. During the time that this department was most active 137 different subjects were filmed, most of them being at least two reels in length and many of them four to nine reels in length. Many of the films produced were used

in propaganda and in instruction purposes in the camps and hospitals of our armies. Among the most successful and valuable of these films may be mentioned the following: Fit to Fight; Diagnosis of Tuberculosis; Fighting the Cootie; Mosquito Eradication; Training the Medical Officer; Come Clean; The End of the Road; and Fit to Fly.

Shortly after the armistice was signed it was decided, owing to the great expense connected with this department, to cease operations so far as the manufacture of moving pictures was concerned; but the films have been kept in circulation, being distributed not only to the military service but, upon request, to civilian institutions for instruction purposes. Some of the films that were made at the Museum are the best available upon the subjects treated and are in constant demand not only by surgeons of military commands but by medical schools and medical associations throughout the country. These films, when available, are loaned without charge for a period of two weeks to medical societies, colleges, and preparatory schools for medical colleges, but the express charges both ways must be paid by those requesting them.

It is hoped in the near future, when funds are available, to resume the making of moving pictures, as they are undoubtedly most valuable both in the instruction of officers and men of the Medical Corps and in presenting the activities of this Corps to the general medical profession and the public. Many of the pictures that have been produced, and could be in the future, are not only of value to the Medical Department from an instructional standpoint, but are just as valuable to the general medical profession.

Anatomical and Wax Models

Prior to the recent war the Army Medical Museum had a valuable collection of anatomical and wax models. The anatomical collection consists very largely of *papier mache* models and manikins, mostly of French manufacture, although there are many injection preparations and wax preparations illustrating anatomy. This collection has been placed in a special room where it is available for study and is very largely used by students of anatomy and medical students to whom the Museum is available. The collection of wax models is probably one of the most complete in the world. It numbers, including those which have been added during and since the war, 780 models. These models are divided into those illustrating skin diseases and syphilis, the pathology of the eye, vaccinia and variola, war injuries, and embryology. The models of the lesions of leprosy, tuberculosis of the skin, tumors, and fifty-five models showing the lesions of syphilis from the initial lesion, genital and extragenital, to the late tertiary manifestation, are especially valuable and realistic. The Baretta group consists of 325 models illustrating almost every disease of the skin, but is especially rich in illustrations of the rarer forms of skin diseases. A very valuable collection of models devoted to embryology is that prepared by Dr. Zeigler of Freiburg, while the pathology of the eye is beautifully illustrated by wax models by Jules Talrich. The Wallis collection prepared during and since the war by Dr. Wallis includes eighty beautiful models representing war injuries and skin diseases observed in the army hospitals during the past two years.

In addition to the anatomical and wax models mentioned, several large collections of plaster masks illustrating facio-maxillary surgery have been received from various hospitals. These models are accompanied in most instances by photographs and drawings descriptive or illustrative of the operations performed, and furnish much material for study and research to surgeons interested in this very important branch of surgery.

Department of Veterinary Medicine

This is a new department in the Museum organized after the Veterinary Corps was taken over by the Medical Department in accordance with the National Defense Act. The object of this department is to collect veterinary material showing the close relationship between the work of the Veterinary Corps and that of the medical profession. Instructions were issued to all veterinary officers upon the subject requesting their cooperation in collecting specimens, and full directions were sent to each officer as to the preserving, packing, and shipping of specimens.

The collection of veterinary pathology has already a considerable number of most interesting preparations and it is only a question of time when it will be greatly augmented. Eventually it will comprise material illustrating comparative animal pathology, meat and dairy hygiene, and animal and food parasites.

Due to the close relationship of the different branches of the Medical Department, the establishment of this new department should prove of great interest to officers specializing in preventive medicine and modern sanitary methods. The collection will also be of great value for purposes of instruction at the Army Medical School in teaching both medical and veterinary officers and will be most interesting to the general public in showing the intercommunicability of disease conditions in man and the lower animals.

During the war several artists were assigned

to duty at the Museum for the purpose of reproducing in colors pathological conditions and war injuries observed in specimens received, and as a result of their work approximately fifty paintings illustrating such lesions were prepared, together with a large number of drawings illustrating various stages in surgical operations performed in army hospital. In addition to the artists employed at the Museum some of the general hospitals were supplied with an artist from the Museum force, and from these hospitals valuable drawings and paintings have been received illustrating operations performed at the hospitals, especially those

All of the cabinets shown in this picture are devoted to facio-maxillary surgery and microscopic exhibits.

in plastic surgery and injuries of the bones, while the artists attached to the Museum unit in France prepared several hundred colored and uncolored drawings and paintings illustrating diseases and wounds occurring in the American Expeditionary Forces. These have been received at the Museum, catalogued, and filed so as to be available for study and inclusion in the Medical and Surgical History of the War.

Department of Entomology

The Department of Entomology has charge of the collection and identification of mosquitoes and other insects concerned in the transmission of disease to man and lower animals and those concerned in the contamination or destruction of food products. The classification of mosquitoes is especially important from the standpoint of the prevention of malaria, yellow fever, dengue, and other diseases due to these insects. Bi-weekly collections are made at all posts at which troops are stationed and these are sent to the entomologist in charge of the department for classification. With the insects is sent a statement regarding the prevalence of any mosquito or other insect-borne disease, with the number of cases and any data regarding the breeding places and habits of any special species of insect. The report on the collection is mailed to the Surgeon of the post and includes the identification of the insects received, together with any information which may be of value in the prevention of the breeding of such insects, or their destruction. The department is responsible, also, for preparing insects for teaching purposes at the Army Medical School and for exhibition purposes in the Museum.

Wide Field of Activities

From this brief description of the collections and work of the Army Medical Museum it is evident that its activities cover a wide field and that for the collections to be available for research and study to the general profession they should be displayed in such a manner as to render them readily accessible. The present building occupied by the Museum is also occupied by the Surgeon General's Library and is totally inadequate in size for housing both institutions. Plans have been made to erect separate buildings for the Museum and Library as a part of the great medical unit which it is hoped to establish in conjunction with the Walter Reed Hospital. When such a building is completed, the collections will be more easily available for study and displayed in such a manner that they can be classified and properly separated. At the present time, owing to lack of room, it is impossible properly to classify many of the groups available for exhibition purposes,

The finest art contributes these paintings, each specially adapted to study and a contribution to science.

and it follows that hundreds of specimens are so crowded as to render their study very difficult.

At the present time the collection in the main hall is composed of models illustrating sanitary apparatus and apparatus used in the treatment of the sick and wounded, ordnance material, hospital and surgical equipment, and pathological specimens, while the galleries are filled with the great collection of gunshot wounds and fractures of bones collected during the Civil War, the very extensive and valuable dental collection, and mis-

cellaneous collections. All of these various groups should be placed in such a way that they can be classified and easily studied, preferably in separate rooms; but, owing to the construction of the Museum and the lack of room, this very diversified material is all crowded into the main Museum hall. An effort has been made to select certain collections that are large enough to fill available space, and these have been placed in separate rooms on the first floor of the Museum. These collections comprise the following groups: Gross pathological specimens; wax models illustrating skin diseases; anatomical models and sections; the historical development of the microscope; and the collection illustrating the method of transmission and treatment of hook-worm disease.

It is hoped eventually to replace all pathological material on the main Museum hall floor with material of general public interest, as specimens of ordnance, missiles, gas masks, sanitary appliances, and sanitary apparatus used in the Army in the prevention of disease. This room will also contain models and paintings of pathological conditions illustrating diseases common to military and civil communities, as malaria, typhoid fever, dysentery, and tuberculosis, and it is planned to arrange these exhibits in such a way as to be valuable in the instruction of the general public in hygiene and preventive medicine.

As has been already stated, there is a great mass of pathological material available for research and it is planned in erecting the new Museum building to provide facilities for research workers who desire to study this material. When space is available, it will be the policy of the Surgeon General's Office to encourage research workers at universities and in the Medical Corps of the Army to take up the study of special subjects at the Museum, where material will be available. At the present time it is impossible to furnish working rooms for research purposes, but a large amount of material has been sent to workers along special lines upon their own request, and such material, if it is available, will always be sent upon request to any recognized research worker with the understanding that credit will be given the Museum in any report that may be published regarding it.

The training of qualified enlisted men as pathological technicians and in museum methods is a function of the Army Medical Museum of great importance. During the war the medical service was greatly crippled owing to lack of qualified technicians for pathological work, and it is hoped that this will be obviated in the future by the instruction at the Museum of a certain number of enlisted men each year who will be capable of performing the technical work necessary at autopsies and in preparing gross and microscopical material for study.

In conclusion, the author desires to state that it is the aim of the Surgeon General of the Army to make the Museum a great instruction and research center, not only for officers of the Medical, Dental, and Veterinary Corps, but for the general medical profession. The facilities of the Museum are at the service of the profession of this and other countries, and any request that may be received for material will be gladly complied with if it is possible to do so. Contributions of pathological or other material are respectfully requested and due credit will be given the donor in the records of the Museum and on the labels of specimens when they are placed upon exhibition.

INDUSTRIAL HYGIENE IN CANADA

In the *Public Health Journal* (Toronto), May, 1920, appears a report of a Committee on Industrial Fatigue of the Honorary Advisory Committee on Industrial Research. This report is preliminary, but shows advanced thinking on industrial hygiene. Some excerpts indicate the grasp of the Committee on the subject. They state:

The science of industrial hygiene is a young science since, while from the early days of industry humanitarians have endeavored to reduce the more flagrant hardships of the worker, it is only within recent days that general recognition has been given to the importance of physiology in relation to the problems of industrial life. It is probably true, as a broad generalization, that the ever increasing volume of welfare work on this continent and in England arose out of general social and humane principles and with possible rare exceptions owed little for direction to scientific and economic evidence. Even the enlightened employer followed his own ideas of what should be done for his employees, without appreciation of the problem as a scientific one calling for investigation and research into the actual facts of the case—into the true relationship existing between the working conditions and the actual output of the workers.

Recognition of the fact that in the science of physiology should be sought definite criteria for the ideals of working conditions was astonishingly late in coming. . . . Equally tardy and obscured in the same way by lack of scientific data has been the realization of the fact that health and efficiency go hand in hand. In an epigram the British Committee state their conclusions that "without health there is no energy and without energy there is no output." It is not too much to say that on application of this great maxim the prosperity of modern industry will largely depend. Sporadic recognition of the principles there has, of course, been; and many employers must have discovered that reforms of working conditions in their plants undertaken in the general interests of the welfare of their employees have not merely been so much unremunerative outlay, but have proved good economic investments, leading to greater efficiency and greater production. Thus, as early as 1894, Sir William Mather, reviewing the actual result on output of an experiment in reduced hours of work wrote, "We seem to have been working in harmony with a natural law, instead of against it, as in the unnatural conditions of men beginning the work of the day without provision required by nature for the proper exercise of their mental faculties and physical powers. *Of this I am assured, that the most economical production is obtained by employing men only so long as they are at their best—when this stage is passed there is no true economy in their continued work.*" That recognition was not general, however, is witnessed by the experience of the war, the early days of which saw frantic efforts to get greater output by increasing the hours of work.

THE NEWER LITERATURE ON HEREDITY

HEREDITY, evolution, eugenics, race improvement are terms and problems which of late with ever increasing frequency have appeared in conversation and literature; and the word "literature" in no sense is meant to be restricted to medical or scientific literature, but properly includes the serious and the trashy novel, the short story of the monthly magazine, and the screen scenario. Writers in the latter group may well be forgiven their ignorance, or their deliberate attempts to weave the thin threads of known facts into complex and glittering textures. However, some of the seemingly scientific writers as well, draw all too freely on their imagination, and among them the medical writer is the worst sinner. Undeniably more than to any other source the layman appeals to the physician for much needed authoritative enlightment on questions of heredity and eugenics. His obligation to possess thorough familiarity with established facts is most obvious. He might easily obtain them from the five volumes mentioned in this discussion. We have grouped them together in a combined discussion, not for the convenience of the reviewer, but because they represent a logical sequence.

There probably does not exist in the English language a more complete, a more readable, or a clearer presentation of the entire problem of heredity than the work of J. Arthur Thomson.[1] This author has the rare gift, manifested in many other volumes from his pen, of elucidating the most complex scientific problems with astonishing simplicity to the educated layman. This volume, at present, has but the one shortcoming that it is seven years old and, therefore, does not include the latest advances in knowledge, which are of particular interest to the physician.

This additional information, however, may be found in the book of Conklin[2] on "Heredity and Environment." A clearer differentiation between supposedly heredity, but actually only environmental influence has been the aim of many scientific investigators in recent years. The result of all this work is set forth by Conklin. In this volume the medical reader will find a most valuable chapter dealing with the possible control of certain phenomena of heredity for the benefit of the race-eugenics; and another chapter on the influence of the relentless laws of heredity and the inevitable effects of environment on the ethical problems of personal responsibility.

From this broader point of view heredity is considered in the volume mentioned as third in the above list, "The Third and Fourth Generation," by Downing.[3] This is a small book which, though primarily written as a text for young people's classes, cannot fail to prove of great value to ministers, teachers, and laymen "who are desirous of obtaining in untechnical language the results which scholars have arrived at in the modern attack upon the problems of evolution." The religious significance of a reverent and thoughtful understanding of that interesting problem, usually called eugenics, is apparent when one thinks of the perfecting of human society as the ultimate goal of the divine plan. Downing deals with his subject in a very original manner. Beginning with a discussion of the pedigree of famous race horses, he gradually builds up the principles of the laws of heredity, demonstrates the visible basis and apparent exceptions of heredity, and concludes with an exposition of the practical prob-

1. Thomson, J. Arthur: Heredity, G. P. Putnam's Sons, New York, 1913.

2. Conklin, Edwin Grant: Heredity and Environment in the Development of Men, Princeton University Press, Princeton, 1920.

3. Downing, Elliot Rowland: The Third and Fourth Generations, University of Chicago Press, Chicago, 1918.

lems of human heredity. The fathers and mothers of the next generation, he states, have a right to a frank presentation of the problems of reproduction and heredity.

Similar thoughts form the basis of an unusually appealing, and one might well say, of an impressive lecture on "Sex Attraction" given by Vaughan[4] to the teachers in the public schools in Michigan and at the Michigan State Normal School. He treats the sex problem in its various normal and abnormal phases in a broad scientific manner and obtains rare lucidity by avoiding the discussion of minor points. It is his sincere belief that proper understanding of the fundamental principles of reproduction and heredity, proper appreciation of health and careful selection of the mate as the really determining factors for the future child, will, more effectively than fear and threat, prompt the adolescent man and girl to preserve jealously their physical and moral health. "While the central purpose of sex attraction is reproduction, this by no means is all. Before there is reproduction there should be something worthy of being produced."

A discussion of the newer literature on heredity would be incomplete without the inclusion of the little volume of Dunlap[5] on "Personal Beauty and Racial Betterment." Part I of this book entitled "The Significance of Beauty," culminates in the thesis that human beauty, considered from the standpoint of the psychologist and not, as is commonly done, only from that of the artist, is the sign and expression of potentiality of the individual to improve the species, both physically and mentally. The unavoidable deduction that the conservation of beauty must, therefore, become the important aim of all efforts in racial betterment, forms the subject of Part II. Careful perusal of this volume can leave in the reader's mind but little doubt that the writer presents his facts and reflections in a most convincing manner to prove his contention.

H. E.

X-RAY LOCALIZATION OF FOREIGN BODIES

THERE are few operations in minor surgery which cause the surgeon, to say nothing of the patient, such great inconvenience as the common condition of an embedded needle in the foot or hand.

The usual procedure is: that x-ray examination is requested, two pictures are made—an anterio-posterior and a lateral—which causes the broken needle or pin to stand out clearly. It is definitely located between such and such land marks, before this and behind that and, to make assurance doubly sure, an indelible pencil mark is placed directly over the foreign body by the aid of a fluoroscope. The patient is taken into the dressing room and promised within a moment or two the needle will be found. An incision is made over the area, retractors are put in which pull the field to one side or the other. Soon the wound is filled with oozing blood. The x-ray pictures are consulted again, a larger incision is made. If the task is undertaken under local anesthesia the doors are tightly closed to keep the patient's expressions of emotion within the operating room; more anesthetic is injected. As a rule, the needle is eventually found, but usually in a location just under a further fascial sheath, or it may be in the walls of the wound itself, covered or pulled to one side by the retractor. To find it a large incision has been made, the tissue has been freely cut during the search, and much time consumed. This fanciful description only too closely follows the usual course of procedure which is absolutely unnecessary.

With the aid of the x-ray the needle can easily and quickly be removed through a small opening and with little trauma to the tissues. The foreign body is localized as before and the skin marked.[1] The patient is not removed from the x-ray room, but is left *in situ quo*. The shades are raised or a bright artificial light is turned full on the operative field. An under-table tube is employed. As a fluoroscope one of the several which has been devised lately can be employed, or if none is at hand, an old fashioned hand fluoroscope box will serve. If this is held firmly to the face, the fluoroscopic image will of course be seen no matter how bright the daylight or the artificial illumination. As a rule, local anesthesia suffices. A small incision is made as before and, as before, the needle may not be encountered. The knife or a probe is put in the depth of the wound. The fluoroscope is brought in position, the x-ray is turned on and the position of the needle noted in reference to the tip of the knife or the probe. In order to do this the part will be gently turned, so that observations are made if possible in positions at right angles to each other. The x-ray is turned off and the wound is deepened in the direction necessary. This maneuver may need to be repeated two or three times before the needle is found, but it more often occurs that after the first incision a forceps can be placed in the wound and, under x-ray guidance, by means of blunt dissection, the needle can be found, grasped, and withdrawn.

An aluminum filter is used. The total length or x-ray exposure is short, so that there is no danger of burning the patient. The tube is diaphragmed down so that the entire fluorescent beam falls within the fluoroscopic screen, thus protecting the surgeon.

The size of the incision is minimal, the injury to the tissue very slight because guided by the fluoroscope, no explanatory maneuvers having been made.

The required instruments are at hand wherever there is an x-ray equipment. The technic[2,3] is simple and can be further simplified by having the assistant wear the fluoroscope and, by means of intermittent x-ray observations guide the surgeon.

Why such a simple procedure has not become more widely adopted, especially in industrial surgery, is difficult to understand.

R. B. B.

MEDICO-HISTORICAL BULLETIN

IN SPITE of the growing interest in medical history there is to this day no weekly or monthly journal of medical history either in this country or in England. The *Annals of Medical History* appears only three to four times a year. The contents of the *Annals* are excellent, but the reading matter is too heavy for the ordinary physician. Also the *Bulletin* of the Society of Medical History of Chicago appears only intermittently, and contains only heavy reading matter. The *Johns Hopkins Hospital Bulletin* often contains articles on medico-historical subjects; the journal as a whole, however, is not devoted to medical history. It is apparent that there is a need of creating a journal or bulletin of medical history which should contain not only original articles but also editorials, historical news items, announcements of new

2. Eastman, J. R., and Bettman, R. B.: X-Ray in War Surgery, Ann. Surg., July, 1917.
3. Stiney, R. A., and Henry, A. K.: Modern Methods of Removal of Projectiles, Surg., Gynec. & Obst., June, 1920.

books on medical history, and other matters of interest in this branch of medicine.

The *Medico-Historical Bulletin*, which has just appeared, seems to have fulfilled this need. It contains many interesting items for those who have the cause of medical history at heart. There is an editorial on Mortimer Frank; an article on Retzius; an illustrated article on Guthrie, the discoverer of chloroform; a book review on "Memoirs of a Nurse," and many other short items. The *Bulletin* is edited by Victor Robinson, whose "Pathfinders in Medicine" and "Don Quixote of Psychiatry" constitute important contributions to medical history. The editor promises to enlarge the *Bulletin* if the readers respond with subscriptions and the students with contributions.

This new publication deserves a place in American medical literature, and there is no doubt that the progressive physician will encourage the editor to develop it into a big journal on medical history.

NEW RESEARCH ON YELLOW FEVER

IN 1918 the International Health Board of the Rockefeller Foundation appointed a commission to study yellow fever in Ecuador. This commission consisted of Dr. A. I. Kendall of the Northwestern University Medical School, Dr. Hideyo Noguchi of the Rockefeller Institute for Medical Research, Dr. Charles A. Elliott of the Northwestern University Medical School, Dr. Mario G. Labrado, and Mr. Herman E. Radenbaugh.

Although all the work done by the Commission has not been published, yet, it is already evident that much has been accomplished in the study of yellow fever. The publication of Dr. Kendall in the Transactions of the Chicago Pathological Society,[1] of Dr. Elliott in the *Archives of Internal Medicine*,[2] and the series of articles published by Dr. Noguchi in the *Journal of Experimental Medicine*[3] show that new light has been thrown not only upon the epidemiology and symptomatology of the disease, but also on its etiology and treatment. Elliott has, in the main, corroborated the classical description of the symptoms of yellow fever given years ago by Guiteras, which can be summarized in five words: Facies, fever, pulse, albuminuria, and vomitus. Elliott summarizes the diagnostic point of yellow fever as follows:

(1) The fact was noted if the patient was a foreigner and not a native of Guayaquil, or had recently arrived from the interior. The local physicians consider it practically impossible that a child born in Guayaquil can grow to maturity without developing yellow fever and, therefore, become immune; or that a susceptible adult can live long in Guayaquil without becoming infected.

(2) A low continuous fever course, with relative bradycardia: a fever of 40° C. or more speaks against yellow fever.

(3) Nausea and vomiting: "black vomit" is practically diagnostic.

(4) Epigastric pain and tenderness are often intense from the beginning.

(5) Development of nephritis is rapid and progressive, with albumin present as a trace on the second day and increasing to from 1 to 3 gm. per liter on the fourth day.

(6) Flushed face, injected conjunctivae, swollen and bleeding gums are characteristic.

(7) The gradual and progressive development of jaundice is noted in the conjunctivae as early as the third day.

Also, Elliott has found that the blood changes in yellow fever are not characteristic; the average red and white blood cell count was about normal, only nine cases showing leukopenia. The same was true with the differential count. The hemoglobin, however, was low; so was the blood pressure.

Kendall seemingly has so far only given a preliminary report, and will publish his main results in the near future. Noguchi, on the other hand, has already published eleven papers and his results are of great import. Noguchi found that a filterable microörganism belonging to genus Leptospira can be recovered from the blood or from the organs of human beings suffering from yellow fever. He has termed this organism Leptospira icteroides. This organism, when inoculated into certain animals, produces the same lesions and symptoms that are observed in the patient from whom the organism is isolated. He has also found that the serum from patients recovering from an attack of yellow fever in Guayaquil has the power to agglutinate and dissolve the organism when introduced into the peritoneal cavity of a normal guinea pig. Noguchi, therefore, believes that there is a strong relation between the organism he isolated and yellow fever; also, he believes that there exists a relation between the Leptospira icteroides and the Leptospira icterohemorrhagia.

Having found the most probable cause of yellow fever, Noguchi experimented with a polyvalent immune serum of high potency in the treatment of an infection produced experimentally in guinea pigs with Leptospira icteroides. The serum was found to be of definite advantage in checking the progress of the infection. When administered during the period of incubation, the serum was found capable of completely preventing the development of the disease, although on subsequent examination hemorrhagic lesions were found in the lungs of the guinea pig which survived. Moreover, the serum modified the course of the disease and, when used in the early stages of infection, prevented a fatal outcome. If the serum was employed after jaundice and nephritis had been present for several days the serum had no perceptible beneficial effect. This, however, was to be expected.

The work of Noguchi promises to be of great benefit to mankind, and the Rockefeller Foundation is to be congratulated on the splendid results accomplished by the members of the Commission.

BLOOD CHEMISTRY IN PREGNANCY

THIS report of Losee,[1] though marked by negative results, is nevertheless of value. In a series of cases of normal pregnancy, toxemia of pregnancy, and eclampsia, he reports that the results in chemical examination of the blood gives no information as to the nature of the condition or the severity of the disease. A great deal of work has been done in the past in the study of the metabolism of cases of the toxemia of pregnancy and eclampsia. From time to time a number of observers have thought that they found the real basic changes responsible for these conditions and the diagnostic chemical findings. Most of the work referred to was done before the recent advances in accurate chemical analysis of blood and urine, and these earlier results have one by one been disproved. The investigation by Losee has been done by the most

1. Losee, J. R., M.D.: Some Observations on the Chemical Examinations of the Blood and Urine in Normal Pregnancy and in Toxema of Pregnancy, Bulletin of the Lying-In Hospital of the city of New York, March, 1920, xii.

improved chemical methods and it appears that his results can be relied upon. His article will save much useless work in other laboratories, and, although his findings were negative, they should stimulate workers interested in this subject to investigate along other lines and the ultimate etiology of toxemia of pregnancy and eclampsia.

The entire March, 1920, issue of the *Bulletin* of the Lying-In Hospital of the City of New York is worthy of being read as it contains many interesting articles. Another article also by Losee on blood transfusion in obstetrical cases is especially important. W. T.

A STAIN FOR FROZEN SECTIONS

IT has always been difficult to obtain a satisfactory stain for use in staining frozen sections for operating room diagnosis. This trouble has recently been much aggravated during the time when it was difficult to obtain stains and laboratory apparatus of all types.

There are two stains which have been most commonly used. The alcoholic solution of thionin has been found quite satisfactory, but nevertheless leaves much to be desidered. Undoubtedly the best stain, when a good preparation could be obtained, has been polychrome methylene blue. Terry* is therefore to be thanked for his publication of a method for the easy preparation of polychrome methylene blue from ordinary methylene blue. He asserts, and McCarthy of the Mayo Clinic verifies his claims, that this polychrome methylene blue gives excellent results. For a description of the method of preparation consult the original communication.

CIRCULATORY EFFICIENCY

THE investigation by Dunn[1] of the effects of multiple embolism of the pulmonary arterioles is very stimulating. The emboli used experimentally were starch granules. When a sufficiently large amount was injected, that is, when a sufficient number of arterioles were plugged, rapid death occurred. The important finding, however, is that a great number of arterioles could be blocked and produce only a slight effect. It should be noted that these emboli lodged in the arterioles, which are end arteries, and not in the capillaries. Each arteriole blocked eliminated from the pulmonary circulation the area supplied by this artery. Even when the function of a large amount of lung tissue was removed from the circulation, aeration of the blood and all other functions remained normal. These experimental data coincide with clinical observations in cases of massive pneumonia in which normal aeration of the blood continues. This work of Dunn was undertaken to investigate the general problem of abnormal physiology which occurs in cases of gas poisoning in which relation many of Dunn's observations are of interest. The investigation described appears to be of greatest general importance. W. T.

REWARDS FOR MEDICAL DISCOVERIES

A DISTINCTLY new departure on the part of British medical and scientific bodies is shown by the action of the British Medical Association and the British Science Guild. A joint committee of these bodies has issued a report in which is recommended awards for medical discoveries. The Committee is highly representative, including among its members such men as Sir Clifford Allbutt, Prof. Benjamin Moore, Prof. J. S. Haldane, Sir Ronald Ross, and Prof. W. Bayliss. The Committee reached the decision that awards should be given and considered that the following different cases should be considered:

I.—*Discoveries involving pecuniary or other loss to an investigator*, either by direct monetary sacrifice or by expenditure of time, or by diminution of professional practice without corresponding pecuniary gains. It is pointed out that a great example is that of Edward Jenner, who occupied himself so closely with the investigation of vaccination against smallpox that he lost most of his medical practice and, also, considerable sums in expense. It is considered that the plea for compensation in such cases is unanswerable, and in 1802 and 1807 the British Parliament fully acknowledged its obligation under this head by giving Jenner compensation in two sums of £10,000 ($50,000) and £20,000 ($100,000).

II.—*Discoveries which have increased the professional emoluments of the investigator by enhanced practice or other means.* Such are, frequently, improvements in surgical operations or medical treatments which lead to increased practice. Another case is that of serums and therapeutic measures, which may have been protected and put on the market. Here compensation cannot be demanded, and pecuniary awards may be generally held to be unnecessary; on the other hand, honors are often, and justly, bestowed upon such work.

III.—*Discoveries which involve neither gain nor loss to the investigator.* This class includes most of the good and sometimes great clinical, pathological, and sanitary discoveries achieved in the world. Here, also compensation can scarcely be demanded, and honors have already often been given; but pecuniary awards should be sometimes bestowed as an act of grace when the value of the discovery to the public or to a government greatly exceeds the emoluments of the investigator. And the principle should hold even in the case of men who were directly paid for undertaking the researches which led to their discoveries, especially when such payment was, as usual, small and the resulting discovery great.

As for the men who should be aided, special attention is called by the committee to the following particular cases which sometimes occur: (1) men who have refused lucrative posts in order to complete their researches; (2) men who have refused to protect their work for fear of limiting its application; (3) men who have carried out investigations for governments for little or no payment on patriotic grounds.

Attention is likewise directed to the following considerations: (1) Honors are usually given as much for clinical success as for medical discoveries, though the latter possess a far wider influence and application than do the former. (2) When given for clinical work or for discoveries under class II, honors often confer distinct pecuniary advantages by enhancement of practice, but for discoveries under classes I and III they have no such effect; and cases are on record where they tend to reduce emoluments by unfitting recipients for certain posts. (3) Most people enter the medical profession at considerable expense, not only from altruistic motives but also to make a living; and it is usually only at a later period that they take up scientific investigation, either from a sense of duty or from predilection or merely because a good opportunity offers. When, therefore, a man finds that his scientific work, however successful and important it may have been, has actually yielded him less emolument than he might have obtained from ordinary clinical work, he naturally feels discouraged and his experience prevents young

1. Dunn, John Shaw: The effects of Multiple Embolism of Pulmonary Arterioles, Quart. Jour. Med., 1920, xiii, No. 50.

men of ability from following his example, and therefore tends to check the prosecution of studies which are of the highest value to humanity. In the public interest the Committee insists on the following principles: (1) That no medical discovery should be allowed to entail financial loss upon him who has made it. (2) That the compensation or reward which he deserves should be assessed as being equal to the difference between the emoluments which he has actually received and those which a successful clinician might have received in the same time. Among the reasons adduced in the report for insisting upon this principle are that few medical discoveries are patentable, and that such discoveries seldom give good grounds for promotion or for administrative appointments in the public service.

On the question of State awards for medical discovery the report says: "Honors, prizes, and medals being bestowed by the King, or by public bodies or by learned societies, are acts of grace which are generally given after much consideration. But the subject of pecuniary rewards comes entirely within the province of the Committee. During the past few years the British Government has disbursed an annual grant of about £60,000 ($300,000) under the Medical Research Committee for subsidizing investigations in progress authorized by the Committee and carried on by workers selected by it. This grant does not remunerate discoveries already made, but proceeds upon the principle of payment for prospective benefits. Another principle, that of payment for benefits already received, deserves close attention and has been recognized in other countries. The Committee thinks that both principles are sound; but they apply to two different classes of research and are indeed complementary to each other."

Payment for prospective benefits is good business only when some return is almost certain; and for this reason subsidized researches must frequently deal with simple and straightforward questions, admitting of immediate experimental reply.

As a matter of fact, however, most of the great medical discoveries were built upon a much more speculative and uncertain basis, and were achieved by men who neither sought nor received subsidies for these investigations. Surely the state should encourage this class of investigation, partly because it costs the state nothing in the doing, and partly because it seems to achieve the greatest results. Obviously, there is only one way to encourage it, and that is by paying for discoveries when made. Payment for benefits received is always not only good business, but also a moral obligation.

The Committee points out that there are at present hundreds of medical men in Great Britain, and they might have said in other countries also, who possess the knowledge, the brains, and the opportunity for private medical discovery, without subsidies, but who do not attempt it because medical research work does not pay even when brilliantly done. The Committee therefore suggests that in addition to assisting investigations in progress, it is proper for the state to remunerate those who have already conferred the benefits of medical discovery upon it, just as it is proper for a patient to pay his doctor. And this policy will be not only an act of justice but an act of wisdom.

The proposals of the Committee in detail are: (1) That the British Parliament should resuscitate the precedent of Jenner by paying compensation when due for losses incurred in achieving medical discoveries. (2) That Parliament should provide an annual sum, say not less than £20,000 ($100,000), for life pensions to be given as rewards to such of British subjects as have made worthy medical discoveries, such pensions amounting to between £500 ($2,500) and £1,000 ($5,000) a year. Such pensions would be preferable to donations in capital and the sums suggested would be sufficient, because men of science seek only such independence as will enable them to employ their talents in the manner they think best. The procedure of allotment should be similar to that used for the Nobel prizes and for the honors and medals of learned societies, that is, full particulars of the work of all applicants should be kept and considered. The Committee points out that Parliament grants large subsidies to soldiers and sailors, has appointed a commission to consider awards to inventors, and allows patents. It should not, therefore, complain if the medical profession, which has done so much for the nation during the war, now asks for some similar consideration.

It is high time that the medical scientific investigator is rewarded as is manifestly his due. When the fact is taken into consideration that, had it not been for medical discoveries, much of the industrial and commercial progress of the world would have been greatly impeded, the need for and justice of recompensing such work is plainly evident. The construction of the Panama Canal would have been impossible if General Gorgas had not put into effect the discoveries leading to the knowledge that the mosquito was responsible for the dissemination of malaria and yellow fever. Again, discoveries in sanitary science have rendered and will further render the lot of the industrial toiler tolerable and comfortable.

This movement in Great Britain is instructive and interesting from another angle. It is a significant sign that the era of preventive medicine is coming into vogue and that state control is perhaps in sight. The establishment of a Ministry of Health was the first and most important step, and state rewards for medical research are only natural corollaries. Sanitation and hygiene, and especially domestic and personal hygiene, will be the ruling maxims of the day and these measures, intelligently directed and efficiently carried out, will tend to prevent disease and in time will prove good business from an economic standpoint.

LONDON CORRESPONDENT.

A SURVEY OF THE NURSING PROBLEM

The American Conference on Hospital Service appointed in March, 1920, a Committee on Nursing. The Committee is making a study of the nursing problem as it exists in the United States and Canada today.

The Committee asks that the readers of MODERN MEDICINE will help them by giving some thought to the following questions. Replies may be sent to M. A. Cannon, Social Service Department, University Hospital, Philadelphia, Pa.

1. In your opinion, what is the value of the three year course for nurses connected with hospitals; the two year course for nurses connected with hospitals; the High School pre-nursing course; the Red Cross extension course; short courses and correspondence courses?
2. Are the principles laid down for nursing education in these courses right or wrong? If right, how can they be improved to meet adequately the nursing need? If wrong, how should the training of the nurses be made right?
3. What use are the graduates of these various schools making of this training? What misuse are the graduates of these schools making of their training?
4. What, if any, is the nurse wastage during training?
5. What, if any, is the nurse wastage after finishing their course?
6. What are some of the reasons for the shortage of nurses today?
7. What suggestions can be made as to changes in the training to make it efficient and not lower the nursing standards.

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

THE ADMINISTRATION OF INDUSTRIAL MEDICINE

INDUSTRIAL medicine needs to be defined. The term as at present used does not suggest to the physician a specialty desirable of acquisition or interesting and profitable to practise; nor to the workman does it mean a complete and dependable medical service.

Most of the materials published under this caption deal with questions of installation, equipment, methods of procedure, or standards of practice—all of which are highly important and constitute a proper field of inquiry on the part of both employers and physicians, and much gain is to be hoped for from the research work of the special committees appointed for this purpose by the American Association of Industrial Physicians. When standards of equipment for given conditions are evolved, and lists of the paraphernalia required are readily available, first aid units or plant hospitals can be installed with a great saving of time and expense over present methods.

But, while it is essential to emphasize a routine that will as far as possible handle the regular work automatically and provide adequate but not too voluminous records of all cases that may become subject to later controversy, the vital consideration in any industrial medical department is its personnel, and a proper rating of a given department is to be had only on this basis.

Perhaps the first factor to be determined in arriving at such an estimate is to learn the purpose for which the medical service was installed and the department to which it is responsible.

We are not inclined to criticize the firm who takes care of accident cases only and who places the chief stress upon remedy and prophylaxis in the event of injury. The whole program of medical care is an outgrowth of the scheme which made industry responsible for its human toll. The law which makes industry responsible for injury presupposes reasonable measures for prevention and needs but slight extension to include the principle of protection of the employer against unfair claims by means of the necessary examinations to determine the physical status of every man undertaking to handle a given job. The elimination of the unfit is merely incidental to placing the right man on the job and may be regarded as a negative consideration as compared with the possibility of avoiding misfits, with their consequent unrest and inefficiency; for it must be conceded that a policy which properly conserves the interest of industry in the long run serves the interests of the men, and the tendency everywhere is to extend the service once it is embarked upon.

We cannot see that industrial medicine, *per se*, differs in any respect from a complete, coordinated health program in any other community, except in the special factors that may be introduced by economic or working conditions. The great variations to be noted in effectiveness of industrial medical service, then, are to be accounted for in differences of organization and personnel. The vital point, given a satisfactory organization, is the attitude respectively of the industrial physician and of the worker.

The physicians themselves present two extremes—in one category being those who are interested in surgery and whose absorption in the physical methods of diagnosis and handling leave them no time for personality studies and those contacts which make for the happiest relationships between patient and surgeon. These men may be great surgeons; their work may rank with the best, and they are not to be unduly criticized. They belong to the same type as the general or special surgeon who finds a social worker essential as a go-between in his work with his patients.

In the other category fall the surgeons who, with varying degrees of success, undertake personally the organization and administration of medical service, handling directly or referring the work as it arises. The chief advantage of the latter type of organization lies in the personal relations it promotes between the medical department and the men. In the hands of a physician prepared for the exigencies of the work and alive to its requirements, an industrial department so administered may become highly efficient. If at the same time he has a faculty for organization, it may exemplify the best type of group diagnosis and complete medical service.

Aside from professional ability, what seems to be the first requirement on the part of the physician in industrial work is the social outlook. He needs to be in sympathy with the men and to sense their needs. If he is not able to do this, a social worker must be provided to supply the deficiency. A social worker is desirable in any case, for science needs to be interpreted in the simplest terms. The profound ignorance of the general public in matters pertaining to health accounts for much of their apparent indifference to their welfare as well as their suspicion of anything that savors of eleemosynary activity. Only recently it has come to our notice that one patient lay in bed in fear that "the blood would rush from her appendix to her head (as she had been told) and kill her"; and another case was led to believe that the aspiration of the pleural cavity done for him was solely to gratify the interest of the physician in charge. Time and some channel should be provided to offer to the patient sufficient enlightenment about his condition to insure his intelligent cooperation; for in any case there will scarcely be better service than the men themselves desire and cooperate to secure.

S. P. M.

EXPERIENCE OF THE MEDICAL DEPARTMENT AT NITRO, W. VA.*

By J. A. WATKINS, M.D., Medical Officer in Charge, Department of Industrial Medicine and Public Health, University of Cincinnati; Medical Director, Lunkenheimer Company, Cincinnati

IN connection with administrative duties, the medical officer was called upon to be responsible for and supervise work for which few physicians or public health officers have had training. Construction was to be supervised, requisitions and purchases authorized, and suitable storage facilities provided. Pit-falls were hidden therein—the most obscure and dangerous being the inclination to fail to concede the relative degree of importance to the administrative function; hence neglect of its proper supervision, organization, and conduct to a greater or less extent. This occurred in the beginning of the work at Nitro, but fortunately was soon corrected. As a result of this experience a separate division for the conduct of this work was organized. It was found that many persons are careless with public property, and great care was necessary to prevent over-requisitioning, misuse, loss, breakage, or possible theft of property.

Laundry Fully Equipped

The laundries of Charleston were unprepared to perform the volume of work that was suddenly asked of them. Also, because of the isolation of Nitro, owing to the total lack of roads and the inadequate railway service, made it imperative that laundry facilities be afforded. A thoroughly modern laundry was, therefore, constructed and equipped. Adequate laundry service was obtained at all times, and no other division was the source of so much benefit, satisfaction, and pleasure as was this.

The Commissary Department

The commissary department for the plant at Nitro and the food stores and stands were operated by the Van Noy Interstate Company under the general supervision of Mr. Hugh Leighton of New York. The choice of equipment and the food purchases for the medical department were made by this company, as was the general layout of the housing facilities for the kitchens, and storerooms. This organization also assisted in the employment of the personnel. There was operated as a distinct division and under the immediate direction of a medical officer, through a dietitian, a hospital dietary division. The plan, equipment, organization, and conduct of this department differed little from such departments in

*The last installment of an article on the experience of the medical department at Nitro, W. Va., published in successive issues of Modern Medicine, beginning in April, 1920.

Explosives Plant "C"
Area 5, GENERAL HOSPITAL
MATERNITY WARD - LOOKING EAST
No. 928 March 4, 1919.
Graham, Anderson, Probst & White Des'ng Eng'rs
Thompson-Starrett Co., Construction Managers

The maternity ward, looking East, of the General Hospital at Nitro, W. Va., adequately furnished with bedroom furniture.

institutions of similar size and character. I believe the provisions were ample, the equipment modern, and the service satisfactory. The operating cost was high, owing to the price of food and labor.

Transportation Facilities

Transportation facilities, like construction, purchasing, and storage, are apt to be neglected by a medical officer engrossed in purely professional duties. He will be ably assisted in such neglect by mechanics, chauffeurs, and passengers, who feel and demonstrate a lack of responsibility for the use and care of motor vehicles which they do not own. As a result, the department will in a short time find such facilities laid up in the garage and the conduct of routine affairs of the division much handicapped for lack of transportation. The organization and conduct of this work at Nitro was, after disagreeable experiences, developed so as to prevent such occurrences.

A four-bed isolation ward, General Hospital.

It consisted briefly in: (1) Assigning each car to one driver alone. (2) Assigning to each car a certain definite schedule of work. (3) Keeping of individual card records of each car as to hours and character of duty, miles traveled, gas and oil consumed, and date of tires. (4) The thorough inspection by mechanics of each car after tour of duty, with written report of driver. (5) General overhauling of each car at regular intervals, even though in apparent good condition.

Vital Statistics

These statistics, though complete and, I believe, accurate,—for the conditions under which they were collected were satisfactory,—are of doubtful comparative value. Among the factors thus affecting these data are the large population turnover, rather restricted age grouping, unusual class grouping of individuals, direct medical supervision of population, and free and unlimited medical attention.

A view of the kitchen in the isolation ward.

The labor turnover during this period of time was at the rate of 620 per cent per annum, far in excess of that occurring in most industries or urban communities. There could hardly be made a more diversified grouping of individuals of different races, color, education, intelligence, and social status, than that existing at Nitro. Owing to the war, the age grouping of the population was unusual. The direct medical supervision given, together with free and unlimited medical relief, brought to the records many diseases and ailments which under usual conditions do not appear in the vital statistics of most communities. To summarize, the factors influencing these data are such that no direct graphic comparison can be made with fairness, either with those obtaining at army or navy camps in the United States or with urban communities. They are, however, of interest to read in connection with the discussion of those activities carried on at Nitro which were designed to have a direct influence on such statistics.

Data in connection with records of the general population are practically as accurate as those obtained in a military camp. The number of men at work was obtained from the employment offices

The Post-Mortem Room in the mortuary building, Nitro, West Virginia.

and the pay roll department, while the number of their dependents was available from the records of the housing office, which assigned living or sleeping quarters to such Nitro residents. through the examination of employees and also of their dependents, the Medical Department was at all times in close touch and cooperation with the employment and housing officers.

Dispensary Admission Rate

In considering these data it should be borne in mind that medical supervision of the total population, together with free medical relief, probably would tend to bring up the dispensary rate. In addition, it was the policy of the department to encourage dispensary attendance even for complaints considered trivial, as it was the belief that such early medical attention would tend to cut down the hospital admission and non-effective rates. The average dispensary admission rate for the period discussed was 3,560.31 per thousand per annum.

Hospital Admission Rate

The same factors which influence the admission rate obtain here, especially the endeavor on the part of the medical department to hospitalize cases, for, though such action would bring up the hospital rate, it would cut down the non-effective rate, and possibly have an influence on the mortality rate. The hospitalization of infectious cases was for obvious purposes and such action in the majority of cases is not carried out in an urban community. Average hospital admission rate for period discussed was 280.69 per thousand per annum. If influenza patients are excluded from these data the rate is 228.59.

Disease Non-Effective Rate

I believe the non-effective rate is indicative of the influence the activities as carried on by the medical department had in keeping men on the "job." The average non-effective rate for period discussed was 5.5 per thousand. If influenza patients are excluded from these data the rate is 3.4. The mortality curve drawn by weeks drops to zero in a number of instances. The effect of the "Flu" epidemic is evident. The average mortality rate was 16.5 per thousand per annum. If deaths from influenza are excluded from these data the mortality rate is 3.8 per thousand per annum.

THE SURGEON'S PART

The first task of any doctor who becomes attached to an industrial establishment is to break down the mistrust of industrial surgeons, said Dr. F. M. Furlong, before the Fourth Industrial Safety Congress of New York State. This opposition he ascribes to the radical change such service implies from a former régime; the fact that it allows no personal choice of physicians; the fact that advice and treatment given gratuitously are not highly regarded; the opposition of certain local physicians who cater to that class of business; and the prejudice of certain workers who feel that their "rights" are being interfered with. To meet the situation the industrial surgeon needs in addition to his equipment in medicine and surgery the art of handling people—that is, he must be temperamentally fitted for the job.

Facts, not theories, are wanted, and in all compensation cases thorough examination and complete records obviate misunderstandings. The work must be organized so as not to upset the shop in case of an emergency, and frequent investigations should be made of all conditions bearing on the health of employees, sanitation, fatigue, recreation, and food. It has been conclusively proved that those plants which maintain an efficient industrial medical service have had a minimum amount of absenteeism, changes, and losses by illness and injury. The advisability of medical service in industry is not a question of sentiment and not a question of humanity. It is a plain business proposition.

NEED FOR INDUSTRIAL TRAINING AT BRITISH UNIVERSITIES

By Our London Correspondent.

Prof. Ramsey Muir made recently an eloquent appeal in aid of funds for Manchester University and in the course of his address he drew attention to the fact that the Ministry of Health can do little unless the universities are equipped to give a sufficient supply of trained medical men and, what he considered still more important, carry on research on a great scale into the problems of disease and the health reactions of industrial life. How shall the country be prepared for the new age of highly scientific industry, unless the universities have the means of training the men who are required? How will a clear understanding be arrived at on the problems of social and political organization unless these are systematically investigated in the objective spirit of the laboratory?

Not one of these great functions can be adequately performed without the expenditure of very large sums of money; but there are two great claims which make at this moment a peculiar challenge to the attention. Before the war men who wanted to be trained in the methods of research flocked to Germany. They went in hundreds from England, from the Dominion and from America; and it is impossible to overestimate the prestige and influence which Germany derived from this fact. The war has stopped the stream, and men are asking why England should not be able to give this kind of training.

Only £500,000 ($2,500,000) is asked by Manchester University for the purpose of fulfilling this function, and it has not yet been subscribed. The amount is paltry by the side of the sums which are frequently given by the rich men of America to its universities. There are plenty of rich men in this country, but there does not seem to be the public spirit which exists in America, or rather, it may be that the rich men, like the medical profession, have not rightly interpreted the signs of the times.

The people of Great Britain are in many ways very conservative and slow to enter into new paths. Their saving grace is that once they do move, they move with rapidity and efficiency. It is to be hoped that all classes will soon recognize the importance of preventive medicine, and of industrial medicine its most essential branch.

THE MEDICAL DEPARTMENT AT E. W. BLISS COMPANY

By DONALD M. GILDERSLEEVE, Medical Director, Brooklyn, N. Y.

THE Medical Department of this company has existed as such for not more than six years, though there existed prior to that time rather less definite arrangements for the care of injured employees.

With the advent of the Bureau of Workmen's Compensation of the State Industrial Commission, the necessity for very greatly broadened scope and systematization of the medical and surgical work for the company became manifest. Particularly was it essential that the system of recording cases and all the details of each case be such as to place at one's finger tips all the data that might be required, and that it be filed in such manner that ten years later it would be quite as readily available.

System Simplifies the Work

Our first impression was one of dread concerning the amount of red tape that would be required, and at first thought it was regarded as certain that the red tape would complicate rather than simplify the situation. This has not been the case. The matter of system, though requiring considerable care and close attention, has been easily managed, and in the end the various forms have made the work much simpler. For convenience in discussion, the service may be considered under four headings: (1) Personnel and duties; (2) kind and amount of work; (3) forms and records; and (4) general observations.

Personnel and Duties

(a) The department is managed by the medical director, who in addition to general supervision, correspondence, and administrative duties, takes charge of the daily clinic for injured employees and visits at their homes such of the injured employees who are unable to report for treatment, though not requiring hospital care.

(b) Cases requiring hospital care and surgical cases for consultation are referred, as will be described later, to Dr. William M. Ennis, our hospital surgeon and consultant.

(c) All eye cases, whatever their nature, are at once referred to our ophthalmic surgeon, Dr. Joseph L. Behan. Dr. Behan has entire control of all eye cases, in addition to his own personal work, his function includes the supervision of the cases of major and minor eye emergencies in the various emergency rooms.

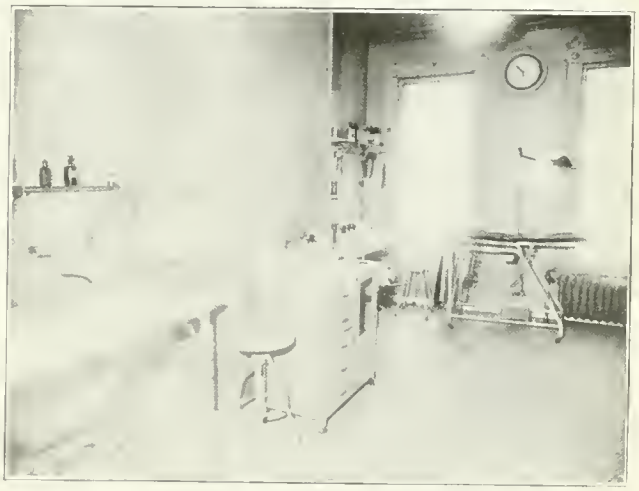
(d) Though not under the control of the medical department, there is an E. W. Bliss Employees' Association, which is conducted by a committee of employees. Cases of illness and injury, exclusive of industrial accidents, among the employees who are members of the Association are treated by Dr. P. A. Renaud, who is paid by the Association. During loss of time from work, due to illness or injury, the members receive six dollars weekly from the Association, and in the event of death one hundred dollars is paid to the next of kin. The company assumes and balances any financial deficit in the accounts of the Association.

The conduct of the Employees' Association rests chiefly with their treasurer, Charles N. Alvarez, who is cashier of the company, and their secretary, Samuel Lewis, one of the senior foremen.

(e) Excluding the plants at Sag Harbor, Paris, and London, as well as the newly acquired plant at Hastings, Mich., and viewing only the works at Brooklyn, which are much the largest, we have four emergency rooms at the present time. Two are in charge of female nurses, and two are intrusted to me. Both of the men's emergency rooms are open day and night, there being a night shift on duty at each. The nurses are women of wide experience and excellent ability, while the men of the department have been recruited exclusively from the hospital corps of the United States Army and Navy. Two of the men served as sergeants with the author, in France, one becoming subsequently sergeant, first class, in charge of the enlisted personnel of the Hospital for Officers, in Paris—Red Cross Military Hospital No. 3. All have had hospital training, and all are thoroughly familiar with the first care in any emergency. By long practice and rather extensive tutelage these men have become highly adept in all manner of surgical dressings that are encountered.

In addition to the nurses and men in charge in the various emergency rooms, there are two clinical assistants and a secretary of the department. The secretary, Mr. Terrell, manages all stenography, typewriting, filing,

The eye work is the direct responsibility of a specialist. Surgical conditions are handled as well as routine tests of vision.



The emergency rooms are equipped with all accessories necessary for the prompt handling of all emergencies.

The office of the medical department is the general clearing house of all the work. All records promptly find their way to the central office.

handling of compensation checks, and other similar work, with the exception of clinic cards, requisition for supplies, and clinic notes. The clinic assistants render assistance in the clinic under the observation and supervision of the medical director, and make up all of our ointments and solutions They maintain direct touch with all telephone inquiries and other desk matters not requiring the personal attention of the medical director.

Kind and Amount of Work

The medical department is divisible into four sections: (a) Administrative and clinical; (b) consultant and hospital; (c) ophthalmological; and (d) first aid or emergency rooms.

(a) All correspondence to the department is promptly placed before the medical director, and all outgoing correspondence is dictated by him. All reports—C-2, C-4, and special—are reviewed and signed by him, with the exception of the C-69, which is written by the eye or ear specialist. The methods employed in making, filing, and using all reports and papers are devised and controlled by the medical director.

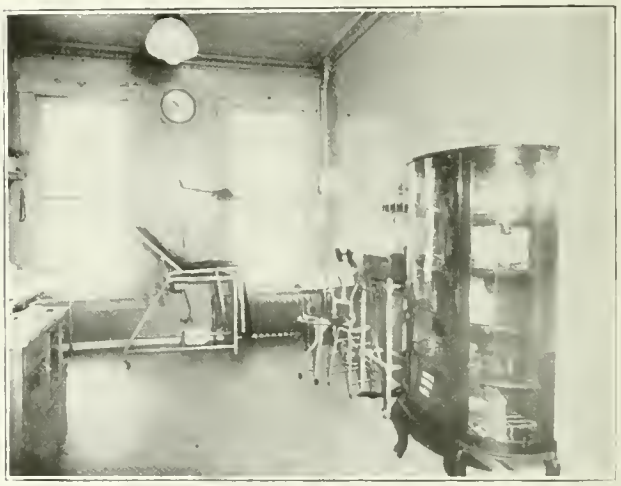
Let us follow the case of Mr. John Doe, who has just sustained a very severe contusion of the dorsal surface of the right foot, at the first metatarso phalangeal articulation. He first reaches the nearest emergency room, where he is given first-aid treatment. While he is there, the emergency man fills out a first draft of the C-2 report, which is the employer's report of injury. The man's shop number, name, address, and injury, together with the disposition of the case, are noted on Form 397 (Fig. 1). The case being of sufficient severity to warrant the personal services of the writer, word is sent to the medical department office and the medical director goes to the emergency room and examines and treats the patient, who is now sent in the medical department automobile to our radiographer, Dr. M. G. Wasch, and thence to his home, where he is treated until he is able to come to the clinic for treatment. He is then referred to the clinic with a clinic pass (Form 426, Fig. 2). In cases sent from emergency rooms directly to the clinic the patient receives this pass from the emergency man.

On the occasion of his first visit to the clinic, his name, shop number, and diagnosis are entered on a Form 347 (Fig. 3). Any further note as to findings or disposition of the case are also entered thereon, under the appropriate date. Instructions given to the patient relative to further appearance at the clinic are likewise recorded. On the occasion of each visit thereafter an entry is made upon the same card to the end that, finally, this card will present a complete record of the man's visits at the clinic. In cases in which an initial clinic record is made, and subsequent home visits take place, such visits are recorded in like manner. Also, record is made on Form 347 of every examination and treatment given personally by the writer in any one of the emergency rooms.

When the patient is entirely recovered, or when his recovery is sufficiently complete to render judicious and possible his return to work, he is sent back to work and, excepting permanent disabilities, his case closed with the insurance carrier.

Records in Hospital Work

Any case sent to our ward in St. Peter's Hospital bears a record on Form 350 (Fig. 4). This is filled out as far as the date of discharge. When the patient leaves the hospital, the date of discharge, diagnosis, and remarks are completed and signed by Dr. Ennis, and the card is



The equipment of the treatment rooms is complete and always in readiness.

returned to the office of the medical department. An initialed copy of this record is sent to the secretary and treasurer of the company, and the original is filed with the other records of the case.

It is not within our province here to discuss the state forms in detail. The C-2 forms are made out by the emergency men, reviewed by a clinical assistant, transcribed by the secretary of the department, and then presented promptly to the medical director for final review and signature. We find very few corrections to be made.

In cases requiring more than two weeks' absence from work a C-4 physician's report is executed and a synopsis recorded on Form 389 for our files. In the case of the C-2 reports carbon copies are retained. We do not retain copies of C-11 and C-111, as the data are all entered elsewhere in our records of any case. The event of a patient returning to work is noted in red on our copy of the C-2 for cross reference. This applies also to the date of admission and the date of discharge of any hospital case.

The clinic is thoroughly equipped in the most up-to-date manner. A great number of fractures are met with, as well as the customary burns, contusions, lacerations and sprains. Cases requiring violet ray, thermotherapy, and

massage have expert attention under the supervision of the medical director.

Initial Physical Examination

The physical examination of new employees is conducted by the medical director. On his first day with the company, the employee receives at the employment office a card, Form 498, both sides of which are shown in Figs. 6a and 6b. The scope of the examination is shown in Figs. 7 and 8 (Forms 497 and 402). The form shown in Fig. 7 is the one used in Brooklyn, while that delineated in Fig. 8 is the one employed at our Sag Harbor works, the Torpedo Testing Station. The difference in requirements explains the difference in forms. On the reverse side of Form 497 are recorded the vision tests, which include:

Vision, O. D. and O. S.—with applicant's lenses.
Vision, O. D. and O. S.—uncorrected.
Binocular, distance.
Binocular, Jaeger.

Records of our physical examinations at Brooklyn are

Space, light and general installation are entirely adequate for the needs of the work. Daily clinics are held. The personnel includes consultants in the several specialties.

entered on Form 496 (Fig. 9). These sheets are kept in a loose-leaf post binder.

Figs. 10 and 11 show the forms used in our monthly and annual statistical reports. A copy of each is invariably sent forward to the secretary and treasurer of the company, to whom the medical director is responsible, while the originals are kept in a loose-leaf post binder, in chronological sequence, an annual report following immediately after a December report.

Analysis of the first one thousand physical examinations, the examinations having been introduced less than a year ago, shows that 96 per cent were accepted. A number of cases of trachoma were found, as well as various valvular diseases of the heart, hernias, varicose veins and ulcers, pulmonary tuberculosis, and deformities. While the physical examination is a very good thing for the company, it has proved a still better proposition for the man himself. With labor conditions as they are at present, it is not always easy to make the employees see that, however.

(b) The surgical cases for consultation or for hospital treatment are referred to Dr. W. M. Ennis, who is retained by the company on a salary basis, as are Drs. Behan, Wasch, and the author. In addition to the hospital cases, which constitute a relatively small number, Dr. Ennis

Dressings and minor treatments are handled in emergency rooms in close proximity to the work, which saves time and insures care of the lesser conditions.

sees at his office an occasional case that is sent to him for examination and opinion, and in some cases for treatment. A case presenting some unusually complex condition which in general work would require a consultation, is seen by the doctor, who submits a report to the medical director. A type of case occasionally met with, and referred to Dr. Ennis for examination, is that of the patient who has some pathological condition not due to any industrial accident, but which he wishes us to believe is due to such cause. Among these are the venereal cases "due (?) to heavy lifting," a case of Hodgkin's Disease attributed to similar cause; old fractures claimed as due to recent injury; or epithelioma held to be caused by the entry of a steel chip, *et cetera*. In such cases it is always better to have two professional opinions on file in the case folder. The consulting surgeon in such cases renders a weekly report to the medical director. These reports are kept in a special file, for ready reference. As soon as the condition of any patient so referred warrants return to the clinic, he is referred back for appearance at the next clinic hour.

During 1919 there were only sixty-three hospital cases. These included several very severe compound fractures, several multiple fractures, hernias of various type and degree, and traumatic amputations, as well as several se-

Dr. Behan, our ophthalmologist, who holds an eye clinic three times a week at the medical department in addition to receiving patients at his afternoon office hour. Dr. Behan controls the work of the emergency men in so far as eye emergencies are concerned, and in appropriate cases controls through the emergency men, subsequent care of eye cases between their visits to his clinic or office. This applies to the use of certain eye drops, ophthalmic ointments or other applications, and in this manner the best cooperation of the patients is secured.

Dr. Behan advises relative to such safety or preventive measures as are in his judgment indicated, and also gives counsel regarding arrangement and character of lighting. In addition, he makes such diagnostic eye examinations as may be required.

Very few of our eye cases have required hospital care; but those requiring hospitalization are sent to the Long Island College Hospital, on the service of Dr. Behan. Several of these cases are of outstanding interest, but to report them here would be to digress from our theme in hand.

Emergency Room Equipment

(*d*) Complete equipment of all dressing materials, instruments, and accessories requisite for the successful handling of all emergencies is always available for the minor initial medical treatment of employees when required, and much loss of time is thereby prevented. The nurse or senior man of each emergency room submits to the medical department office each Monday morning a properly prepared requisition for supplies. This list is then reviewed by the medical director, revised if necessary, and turned over to Mr. Hutty, whose function it is to prepare the lots for transfer to the emergency rooms.

Thorough instruction and considerable experience have

resulted in a thorough knowledge on the part of those stationed in the emergency rooms of when to send a man immediately to the hospital; which cases should be sent home; which should be at once sent for radiographic examination prior to examination by the medical director, and which cases require the immediate attention of the medical director. Further, they are well acquainted with all of the "don'ts" relative to treatment and other matters. A pass issued by an emergency man or nurse is honored, without further process.

The forms which are used in the emergency room work have already been discussed. Those concerned readily appreciate the importance of an accurate and prompt execution of these forms, and no trouble is experienced by the office in this connection. An occasional bulletin is issued to all of the emergency rooms, and frequent inspections are made; in the main, however, very little correction is found necessary.

In the absence of the medical director the emergency rooms are under the control of Mr. Lamberson. Mr. Lamberson, from time to time, also receives instructions for transmission to the emergency rooms. General orders are kept on file also in the medical department office in such manner that they may be readily consulted should occasion require.

Necessary Forms and Records

Most of the forms used have been mentioned. Several others, of less importance in this discussion, include a medicine envelope; forms concerned with the requisition, purchase, receipt, and disbursement of supplies; a special voucher for reimbursement of carfare to an injured employee; prescription pads; special labels; and correspondence stationery. Upon discharging a case, the completed records are filed together in a folder, with the file of closed cases. Only records in "live" cases are kept in the several special record files.

A careful record of checks issued in payment to injured employees is kept. These checks are sent to our office by the insurance carrier and, immediately upon their receipt by us, entry is made in Mr. Terrell's lists. This covers the date of issuance and date of our receipt of the check; its number; the amount; the name of the payee; his case number, and the period for which it pays the compensation. This entry is checked off when the draft is turned over to the patient, date of delivery being noted.

General Observations

Division of the work of the physicians in the manner above outlined yields most satisfactory results. Only one full time surgeon is required. There is a minimum of conflict between several duties each of which requiring prompt performance. The interests of the patient are protected in the fullest measure. Expense to the company is very moderate, considering the nature and amount of work accomplished.

This work offers one a remarkable opportunity for the study of human nature among the workingmen. Of course, all types and all kinds of situations are met with,

some highly disconcerting, while others are humorous. On the whole, the great majority of the workers are reasonable, good-willed men, whose sole desires in connection with their injuries consist of securing cure of the injury, payment of such compensation as is provided by law, and early return to work. We have, on the other hand, been regarded unfavorably for not having cured epithelioma in three days; for one or two infections in patients failing

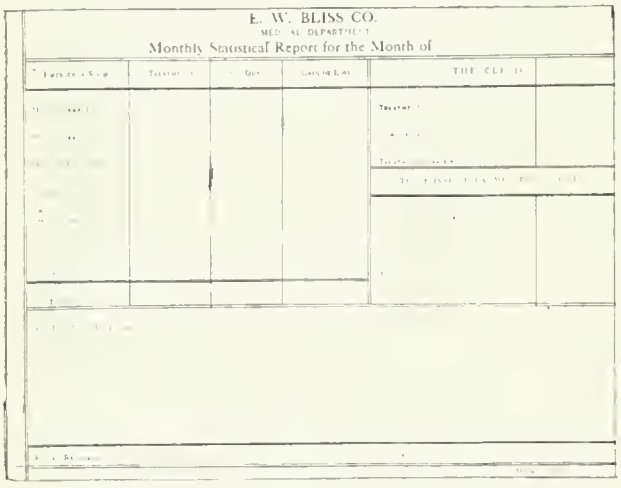

Fig. 10 The data obtained from the daily sheets are compiled in the monthly statistical report.

to report for treatment; and for not having consented to engage an eminent surgeon to perform an operation that our surgeon could perform quite as well. To get the best results, in many respects it is necessary to meet these men and women—we do not employ a great many at this writing—with tact and diplomacy. Both kindness and firmness are absolutely essential. Everything possible should

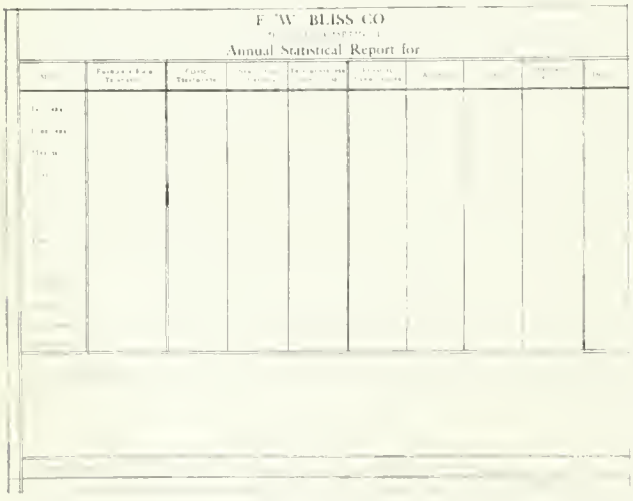

Fig. 11. The annual reports bring together in tabulated form all essential features of the work accomplished by the medical department.

be done to maintain the patient's morale, his self-respect, and anything that can be fairly and consistently granted in the direction of compliance with any special wish should be done. He must be made to see that your interest rests wholly in his welfare, without, however, for a moment countenancing in any way anything distinctly unreasonable. The patient should have the benefit of any doubt, but the "doubt" should be cleared up as speedily as may be. Everyone in the department can aid materially in improving or maintaining properly the psychology of the employees and this is, as we are coming to realize more and more, a very important matter.

One must guard against being too automatic in this work. The treatment of many hundreds of similar cases tends to refer too much of our activity to the cord, rather than to the cerebral cortex. We must be ever watchfully on the lookout for the exceptions. These are the most important of all, requiring special treatment and diagnostic measures. These exceptions are not as exceptionally exceptional as one might suppose.

In the course of the past six years we have built up a very full library of radiograph pictures. Virtually every bone in the body is represented fractured in various ways. We find that it is possible in a large proportion of cases to diagnose incomplete fractures by a very careful examination as to exact area and degree of tenderness. There is nothing magical, nothing clairvoyant, about this; it is far from infallible, but it does give correct results in a large majority of cases, as radiographic examinations have proved.

It follows that our treatments have become, within judicious limits, more or less standardized. In certain types of injury we have developed special forms of treatment; but in the main the treatments are quite orthodox in their conformity with generally approved therapy.

INDUSTRIAL NURSES ORGANIZE

Are you an industrial nurse? Are you interested in industrial nursing? Are you an employer of labor? Are you interested in industry? If you are, do you belong to the Industrial Nursing Section of the National Organization for Public Health Nursing?

An Industrial Section of the National Organization for Public Health Nursing was formed at Atlanta, Ga., April 10, 1920. The By-Laws state: (1) The object of this Section shall be to stimulate interest in the special problems of the industrial nurse and to provide a forum for the discussion of such problems. (2) Any member of the National Organization for Public Health Nursing may become a member of this Section by sending her name to the secretary of the Section for enrollment as a member.

Employers are eligible to membership in the National Organization for Public Health Nursing, and if they become members they may join the Section.

Nurses registered at the Atlanta convention may join. If you would like to become a member, join the National Organization for Public Health Nursing. A subscription to *The Public Health Nurse* is included in membership. This is the only magazine devoted exclusively to the subject of public health nursing.

The National Organization for Public Health Nursing serves the employer as well as the nurse in industry. From its central library and forty-four state library centers literature on the subject of public health nursing may be obtained. Nurses desiring to register are requested to send their names to Florence Swift Wright, chairman, Industrial Nursing Sec., Nat. Organization for Public Health Nursing, 156 Fifth Ave., New York City.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

SOME ACCOMPLISHMENTS OF THE PAST

IT IS doubtful if even the professional public health worker always realizes fully how considerable have been the concrete accomplishments of sanitary science during the past two decades. It may contribute to a more confident and aggressive prosecution of the public health campaign to review the statistical record as it concerns a few of the diseases which have lent themselves most readily to practical measures of control.

The death rate from typhoid fever in the Registration Area has been reduced from 35.9 per 100,000 to 13.4 per 100,000 in 1917; the death rate from diphtheria and croup has been reduced from 43.3 per 100,000 in 1900 to 16.5 in 1917; the death rate from diarrhea and enteritis has been reduced from 133.2 in 1900 to 64.0 in 1917; while the death rate from tuberculosis has fallen in the corresponding period from 201.9 to 128.9.

We have thus a reduction, in less than twenty years, of more than 22 points per 100,000 for typhoid fever, of more than 26 points for diphtheria, of more than 69 points for diarrhea and of 73 points for tuberculosis—a total of 190 points in all. This means a saving of approximately 200,000 lives a year in the United States as a whole.

In other words, the reduction in these four diseases is saving to this nation *every year* more lives than were lost by our Expeditionary Forces in all the battles of the late war.

The Promise for the Future

The prospects for the future are so bright as to warrant a confident hope of even greater triumphs than have been won in the past. The causes of infant mortality which operate before birth, at birth, and during the first month of life are only just beginning to be attacked by prenatal medical and nursing care. The problems of nutrition are for the first time being dealt with in definite and organized fashion. The campaign against tuberculosis promises to take on new life and vigor. The campaign against venereal disease has only been initiated on any broad and effective scale during the past two years. Malaria and hookworm disease have been proved to be definitely controllable; but they have actually been controlled only in restricted areas. Diphtheria antitoxin has not yet accomplished the results which it is capable of yielding; and pneumonia serum has been scarcely used at all. Cancer should prove as amenable as tuberculosis to an organized effort for education, early diagnosis and prompt treatment—in this case surgical in nature; while the potency of hygienic education and systematic medical examination of the supposedly well promises tangible results in the reduction of the degenerative diseases of adult life.

It will be even more true in the future than in the past that "Public health is purchasable," and that "within natural limitations any community can determine its own death rate."

The Principal Obstacle to Progress

Such are the brilliant possibilities of the modern public health campaign. The public fully appreciates these possibilities and is generally willing and eager to provide the resources which are needed for a far reaching offensive against preventable disease. The factor which more than any other condition holds us back today is the lack of personnel.

Cities on every hand are ready to adopt a comprehensive public health program; but they cannot find properly qualified and inherently able health officers. Towns by the score are waiting months to secure trained public nurses. Health center plans are held in abeyance and existing infant welfare clinics are cutting down their work because men and women cannot be found to do the work. Delay and discouragement, or the still more serious setback that follows the attempt to operate with incompetent and untrained personnel,—these are the stumbling blocks in the path of the new public health.

Meanwhile, even our leading schools of public health are turning out a dozen graduates a year when the demand calls for hundreds. Even the discharge from the army of hundreds of newly trained bacteriologists did not for a moment produce a glut in the market. Students who have taken the Doctorate in Public Health or the Doctorate in Philosophy in Public Health have had half a dozen positions each to choose from at three to five thousand dollars a year.

The appeal must be made boldly and unceasingly to the college graduates of the country that they may come in increasing numbers into this field which lies fallow for the harvest. A one year course for the Certificate in Public Health, or a three years' course for the Doctorate, will open the door to a career full of public usefulness and personal satisfaction. The greatest emphasis, however, is to be placed upon the fact that we need young medical graduates who may catch the vision of community service, and fit themselves by one or two years of post-graduate study for the profession of public health. There is need for men in clinical medicine, there is need for men in the laboratory, but there is an even greater need for men of the right type to lead in the organization of the greatly expanded state health service which must develop in the coming year.

EDITOR.

THE PUBLIC HEALTH CENTER OF ALAMEDA COUNTY

By MISS ANNIE FLORENCE BROWN, Member Executive Committee, the Public Health Center, Oakland, Calif.

FOREMOST among the many lessons America has derived from our recent war stands the importance of the development of public health. Attention has been called to the health of our Nation by the fact that 35 per cent of America's young men of draft age were rejected from military service by our first physical examination; an additional 15 per cent were returned home after entering the training camps. This shows that approximately one-half of America's youth were found physically unfit for war service at the time of the Republic's greatest need.

From all sides has come the question: "What can be done to remedy this condition?" The best answer to this is: *"That the only protection of individual health is through community public health."*

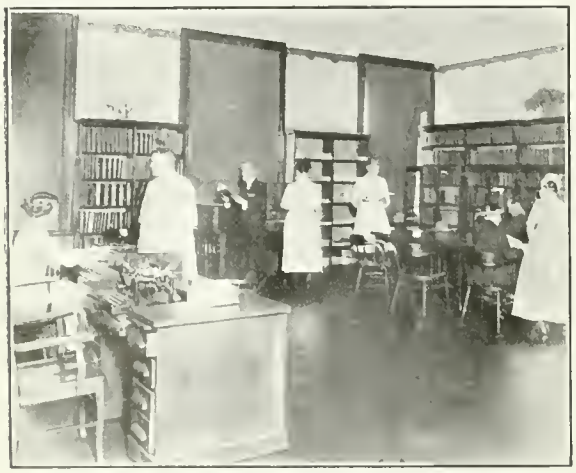
The building of the Public Health Center of Alameda County, situated in Oakland, Calif.

Health Centers a New Development

The most logical means of continuing the progress made in public health during the period of the war is the coordination of forces promoting public health and developing them into the modern institution known as the Public Health Center.

The war psychology that inspired large groups in community service during the years 1917 and 1918 is now being utilized for community health service.

The Public Health Center is an organization which consolidates, administers, and increases the efficiency of public health, relief, welfare, and charitable work in the community. This is done by: (1) The consolidation, maintenance, and improvement of public clinics of all kinds; (2) the installation for their use of complete scientific laboratories; (3) the conducting of popular education in hygiene and sanitation; and (4) the elimination of duplication and overlapping of effort in the field of community service by coordinating relief and social service agencies through the maintenance of a central clearing house or confidential exchange.



Patients waiting for admission to the Social Service Department, Public Health Center of Alameda County.

Origin of Alameda County Health Center

Three factors were foremost in the minds of those who were present at the initial meeting held in Oakland, Calif., in 1918, for the organization of the Alameda County Public Health Center. They were (1) the need for better health instruction in our public schools; (2) the establishment of adequate dispensaries in the community; and (3) the coordination of existing public health organizations in the county, chief among which was the Anti-Tuberculosis Association, which had been well established for a decade.

Patients waiting at admission desk. Day and evening clinics are maintained.

In June, 1918, a preliminary meeting, called for the purpose of organizing, was attended by the following persons: Mr. Fred M. Hunter, superintendent of schools of Oakland; Dr. Howard Morrow, clinical professor of dermatology, University of California Medical School; Dr. William E. Musgrave, director of hospitals, University of California; the late Dr. A. S. Kelly, then president of the Board of Education of Oakland; Miss Ethel Moore, president department of recreation of Oakland; Mrs. F. C. Turner, chairman of Alameda County Women's Committee of the State Council of Defense, and Miss Annie Florence Brown, former president of the Oakland Board of Education and secretary of the Alameda County Anti-

The Center operates a children's dental clinic where hygienists work with full-time dentists.

Tuberculosis Society. As a result of this meeting it was determined to urge that the health work of the public schools of Oakland and Berkeley, together with the work of the Anti-Tuberculosis Society of Alameda County, be placed under the direction of the proposed Health Center, which should be supervised by a director professionally trained in public health. The organization of the proposed new Health Center was outlined as set forth in Chart I.

It was further determined at this meeting to develop the Health Center under the direction of an advisory committee. The object of an Advisory Committee was three-fold: To avail the Health Center of scientific advice on technical subjects; to assure permanency and continuity of policy; and to relieve an institution local in its work from any cross currents of a purely local nature. The natural source of the personnel of this Committee was from the faculty of the State University. A presentation to the Board of Regents of the University of California of the plan of organization and operation of the proposed Health Center resulted in the appointment from the faculty of the Medical School and Department of Economics of the University of the following Advisory Committee: Dr. Herbert C. Moffitt, dean of the Medical School; Dr. Howard Morrow, clinical professor of dermatology; Dr. William E. Musgrave, director of hospitals; Dr. Jessica Piexetto, professor of social economics, and Miss Lucy Stebbins, assistant professor of social economics, all of the University of California.

Upon the appointment of the Advisory Committee each of the agencies in Alameda County performing health, relief, and welfare work was invited to send two representatives—one a professionally trained worker, the other a non-professional representative, to hold membership in and join in organizing the Board of Governors. Official representatives were sent from: Ten hospitals and dispensaries, ten relief organizations, two educational institutions, four public school systems, three chambers of commerce, six public welfare organizations, two probation boards, two labor organizations, four health departments, one bureau of occupations, the Alameda County Medical Association, the Alameda County Dental Association, the Alameda County Nurses' Association, and the Alameda County Psychopathic Association.

At this first meeting of the Board of Governors a Constitution was adopted defining the duties of delegates and vesting in the Board of Governors certain power to deal with questions of general policy. The Constitution sets forth the basis of organization. It is printed herewith.

Constitution of the Health Center

Article I

Name.—The name of this organization shall be "The Public Health Center of Alameda County."

Article II

Purpose of Organization.—The purpose of this Health Center shall be the affiliation in one centralized organization of such social agencies in Alameda County performing health, relief, and welfare work as may desire to become members, and by the coordination of the work of these agencies to avoid duplication of effort, to increase efficiency in administration and to bring about more widespread education in preventive medicine.

Article III

Membership.—The membership of this Health Center shall consist of such organized agencies engaged in health, relief and welfare work in Alameda County as shall subscribe to the principles thereof.

There shall also be contributing members, consisting of annual and life members, without votes. Annual members shall be those who pay annual dues of Five Dollars; life members shall be those who pay not less than One Hundred Dollars.

Article IV

Board of Governors.—The Board of Governors shall constitute the governing body of this Health Center, which said Board shall be composed of representatives from the several agencies having membership therein, each agency electing one representative, except that where such agency has a professional executive it shall be entitled to two representatives. One shall be selected by such agency from its non-professional members, and the second shall be its professional executive.

The members of this Board shall hold office for one year and thereafter until their successors are elected.

Nine members shall constitute a quorum.

The Board of Governors shall deal with all questions of general policy and management of the Health Center, and shall have full control thereof, save as the same is hereafter vested in the Executive Committee and in the Advisory Committee.

Article V

Executive Committee.—There shall be an Executive Committee consisting of seven members elected by the Board of Governors, with the advice of the Advisory Committee.

The Executive Committee shall be the administrative body of the Health Center and shall control the finances thereof and shall exercise such power as is usually exercised by Boards of Directors, subject to the powers herein expressly given to the Board of Governors and to the Advisory Committee.

The members of the Executive Committee shall serve for four years; provided, however, that the Committee

The children's recovery room was furnished by the pupils of the "Rainbow Club," University High School, Oakland, Calif.

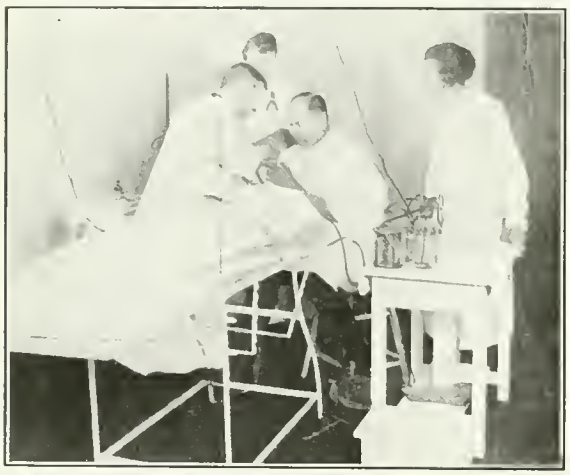
as first constituted shall choose by lot two of their number to serve for one year, two of their number to serve for two years, two of their number to serve for three years, and one of their number to serve for four years. Thereafter as new members are appointed each shall serve for a period of four years.

ARTICLE VI

Advisory Committee.—There shall be an Advisory Committee appointed by the Regents of the University of California from the faculty of said University. The majority of this Committee shall be members of the faculty of the Medical School of the University of California. This Committee shall act in an advisory capacity to the Executive Committee on all questions affecting the work of the Center; and the selection of the Director of the Center and heads of departments shall be made only by the advice and with the consent of the Advisory Committee.

ARTICLE VII

Director of the Center.—There shall be a Director of the Center appointed by the Executive Committee. The Director shall be the Executive Officer of the Center, and shall direct the several officers, departments and branches



A tonsil operation under way at the Public Health Center of Alameda County, Oakland, Calif.

of the Center. Heads of departments and all officers of the Center subordinate to him shall be chosen only upon his recommendation with the approval of the Advisory Committee. He shall exercise such other powers as shall be conferred upon him by the Executive Committee.

ARTICLE VIII

Amendments.—This Constitution or the By-Laws of this Center may be amended by a two-thirds vote of those present at a regular or special meeting of the Board of Governors; provided, that written notice of such proposed amendment shall have been previously given by mail to each member of the Board of Governors at his last known address at least forty-eight hours prior to the time of such meeting.

Judge Chas. E. Snook, president of the Alameda County Anti-Tuberculosis Society, was elected chairman of the Board of Governors.

Details of administration are left to the Executive Committee of seven members elected by the Board of Governors. Mr. Harrison S. Robinson was elected chairman of the Executive Committee.

The Executive Committee, working in conjunction with the Advisory Committee, selected as director of the Public Health Center of Alameda County, Dr. Richard A. Bolt, formerly chief of the Bureau of Child Hygiene of Cleveland, O.

After being with the Health Center for six months, during its organization period, Dr. Bolt was called to Washington, D. C., to fill the position of general director of the American Child Hygiene Association. This vacancy was immediately filled by Dr. Alvin Powell, a graduate of the Medical School of the University of California, who, after a number of years of successful practice, gained a reputation for medical organization while acting as Lieutenant Colonel for Mobile Unit Number 1 which rendered operative service in France during our late war.

Temporary Health Center Building

The main Health Center is temporarily housed in a building at one time owned and occupied by the former Oakland College of Medicine. Here had been conducted for more than twenty years various clinics, both medical and dental, by a group of public spirited physicians who contributed not only their time, but also the funds for maintaining same. In a most generous and progressive spirit this Medical College presented the site, building, and equipment to the Public Health Center.

The Alameda County Medical Association has its headquarters in the Health Center building and has located therein its medical library and trained librarian. This medical library forms a nucleus from which will develop the educational work in hygiene, sanitation, and preventive medicine.

At present thirteen different clinics are being conducted in this building under the supervision of the Health Center.

Method of Operating Clinics

Invitations were issued to all members of the Alameda County Medical Society asking their cooperation and requesting them to state in what department of medicine they desired to work. These invitations met with unanimous acceptance. Clinical committees have been organized from the physicians of Alameda County. The staff is divided into a Consulting Staff and a Clinical Staff. Each clinic is under a chief from the Consultant Staff assisted by a sub-chief from the Clinical Staff.

Although clinics are operated mainly for school children, a full line of clinics is also maintained for adults. Persons occupied during the day by business and industry are

served at night clinics. Admission to these clinics is not entirely free, as a fee of twenty-five cents is charged each patient at entrance with a ten cent charge for all subsequent visits. Treatment at night clinics, however, carries a charge of fifty cents and one dollar.

Before admission to a clinic, a careful examination of

The scientific laboratory serves both consultant and clinical staffs, and is always available.

each case is made by a well organized social service department (Chart II).

As each case leaves the Health Center it is carefully followed up by the Department of Social Service. A number of large hospitals in our community have turned over their social service work to the Health Center. The new County Hospital now under construction plans to have all admission of the patients through the Social Service Department of the Health Center.

In connection with this department there is being de-

veloped a clearing house or confidential exchange for clinical, nursing, and social service activities for other agencies in Alameda County as well as for the Health Center. A uniformity of record system and organization will thus coordinate the social service work of the county.

Main Health Center Building

A site covering a city block located at the civic center of our community has already been purchased. An active campaign is now being conducted under the chairmanship of Dr. Daniel Crosby, former health officer of Oakland, for a fund of $100,000 for a modern building.

The plans for this proposed building contemplate a two-story U-shaped structure with a central court. On the first floor will be the lobby, waiting rooms, and administrative offices. In one wing will be located rooms for dental, medical, surgical, and orthopedic clinics. Separate clinics will be provided for tuberculosis, with special waiting rooms for men and women. Adjacent to this clinic will be the executive offices of the Alameda County Tuberculosis Society.

The opposite wing of the building will be devoted to clinics for school children. In this wing will also be found the administrative offices for the health development work of the public schools, including offices for the public school nurses. This department will be maintained largely by school funds.

An important feature of the new Health Center building will be the large modern dental clinic and dental laboratories, where dental hygienists will work in conjunction with full time dentists in preventive dentistry as well as in actual dental operations.

On the second floor will be located the library and meeting place for the Medical Association of Alameda County. On the same floor lecture halls well equipped with stereopticon and moving picture apparatus will afford ample opportunity for popular lectures on public health, hygiene, and sanitation. During the day hours will be given talks to all the grades of school children. The evenings will be utilized for lectures to adults engaged in industries during the day.

Provision is being made for a department of dietetics

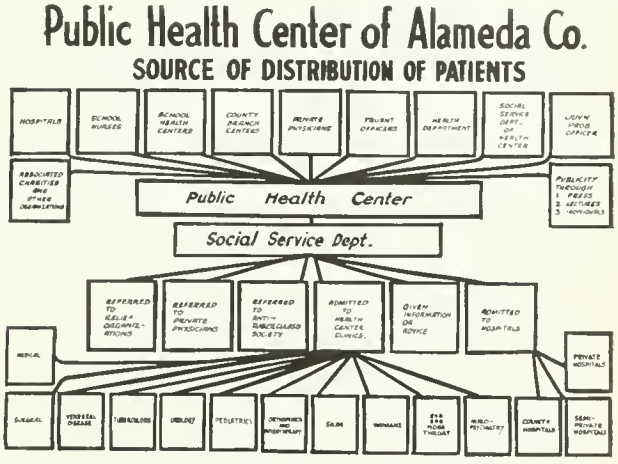

Chart II. Although operated mainly for children, full clinical provision is made for adults, open in the evening as well as in the daytime.

where instruction will be given to mothers in the value of different foods for children as well as for the sick.

Branch Health Centers

Although the main Health Center is situated in Oakland, a city of 216,361 population, the largest city in Alameda County; Berkeley, the seat of the State University, with population of 55,868, has also its Health Center which has developed from a well organized institution known as the Berkeley Dispensary. Soon Alameda, one of the sites proposed for the Pacific Coast Naval Base, with a population of 28,806, will also have its Health Center.

Numerous small towns remote from the populous districts in Alameda County have called upon the main Health Center for supervision in establishing Branch Health Centers. A number of these are now in operation, one in San Leandro, a town of 4,500 population; another at Hayward, population 4,000; a third at Niles,

population 1,500. This latter Health Center will serve four or five smaller towns covering a district known as the Washington Township. Plans are now in preparation for the establishment of a Health Center at Livermore, population 2,450, where is located a splendidly equipped institution for tuberculous patients, known as Arroyo Sanitarium.

Health Centers in Schools

In congested districts of the city of Oakland, where the foreign element predominates, branch health centers known as "Well Baby Conferences," "Children's Clinics," "Malnutrition Classes," and "Dental Clinics" have been established directly in conjunction with the public schools. These clinics are often operated in cottages upon the school premises and under the direction of the Director of the Health Center assisted by the school nurse. As the director of the Health Department of the Public Schools is also the medical head of the Health Center, a fully developed plan of Branch Health Centers in public schools will soon be installed. Ultimately a school health center, under the supervision of the school nurse, will serve the children of three or four schools, thus carrying out the idea of a health center to a unit of population. Dr. Edna Bailey, director of science of the public schools of Oakland, has rendered most valuable service in the organization of the school Health Centers.

As the Health Center serves the population of the entire county, both children and adults, the County Board of Supervisors appropriates annually a sum of money for the maintenance of the clinics. A portion of the salary of the Director of the Health Center and the entire salary of the twelve school nurses are met by the Oakland School Department. The Oakland Chapter of the American Red Cross has given a generous donation toward the equipment of the Health Center. Within the next month five additional dental chairs, including complete dental equipment will be installed in our various Health Centers (Chart III).

A marvelous and ever increasing source of revenue is obtained from our former Red Cross shop, which at the close of the war was given to the Health Center for operation. On invitation from the Health Center the public schools of Oakland were asked to cooperate in gathering old clothes and salvage of every description. The shop is now known as the Junior Red Cross Shop, and each month yields a steady income of over $3,000, all of which is used for the health work of the children of our community. From a single drive of one of our high schools $2,000 worth of material was collected in one day. Much credit of this shop is due to the untiring efforts of its manager, Mrs. Brady Wolfe, who also rendered valuable war service to our community.

Ofttimes a monthly sum is given by the main Health Center to an adjacent town to start a branch health center, under the supervision of the Director of the County Health Center, but these towns as soon as possible finance their own health centers.

Until the community has learned the value of these health centers and asks for their establishment it is thought best not to urge too large an appropriation for this purpose. So, at present, most of these school health centers are financed by women's clubs, prominent among which are: the Oakland Club, the Home Club, Collegiate Alumnae, and New Century Club. The Mothers' Clubs are lending their effort in many directions to make these school health centers a success.

The Ebell Society of Oakland has taken upon itself as its Community Service work for 1920 the construction of the children's wing of the new health center building.

The greatest service which the people of Alameda County foresee for the Health Center is to aid in fostering the healthy growth and the sound physical development of every child within its border.

TRADE UNIONISM AND TEMPERAMENT

Whether the problems of reconstruction are to be charged to the war, to bad morals, or to the faulty education, industrial problems are to be dealt with in no narrow spirit, is the opinion expressed by E. E. Southard, M.D., *Mental Hygiene*, April, 1920.

The article is a plea for an inclusion in the field of industrial medicine the neglected field of mental hygiene. Trade unionism, as defined by the late Professor R. F. Hoxie, is discussed as a phenomenon of mass psychology. The four types of trade unionism are considered by Southard to conform rather neatly with the classical types of temperament, and the genesis of the different trade unionism is due in great measure to temperamental trends. They interpret behavior along simple lines of direct action, and by applying modern psychiatry to the study of these problems, attempt to meet them with a better understanding and very much more sympathy, the logical method being to direct the choleric level into the channels of the "uplift" or "sanguine" temperament.

MUST WE PREPARE FOR A PANDEMIC OF SMALL-POX?

By WALTER C. ALLEN, Surgeon to Rochester Works, General Electric Company, Rochester, N. Y.

INTERNATIONAL quarantine officials, sanitarians, and epidemiologists express uneasiness regarding the very unsatisfactory condition as regards small-pox throughout the world. Two decades have passed since the notable epidemics of 1901 to 1904 visited a great number of great centers of population throughout the world. A long period of immunity has made the public everywhere careless regarding vaccination. In fact, the percentage of refusals of vaccination is on the increase in most of the civilized countries of the world.

Signs of Approaching Storm

There have been a number of localized epidemics during the last two years and health officials are beginning to ask themselves if these are rumblings of approaching storm. Here, in America, the Canadian epidemic, coming late in 1919, called the matter forcibly to our attention. It will be recalled that more than two thousand cases were reported from Canada in 1919, of which more than seven hundred developed in Toronto. In addition to twenty-six centers in the Province of Ontario where cases were reported, considerable numbers of cases were reported from the provinces of Quebec and Manitoba. In the Province of Ontario vaccination is reported to be compulsory. On this side of the border we have no such law.

It will also be recalled that late in 1919 the United States government declared a quarantine against Cuba because cases of small-pox were taken off a vessel arriving from the West Indies.

Reports in April, 1920, advised us that small-pox is epidemic in the states of Sonora, Chiapas, Oaxaca, Morelos, Chihuahua, and Guerrero, Mexico, and the collapse of the Carranza government will not help matters at all. In fact, they may be expected to go from bad to worse.

In the United States we have not been without warnings. There were a number of cases in California in 1919, as reported by Gillihan,[1] who concludes from his studies that small-pox is increasing throughout the world, both as respects incidence and mortality. The cases are of a mild form. However, he believes that severe reactions following poor methods of vaccination are universal. In view of the fact that the immunity conferred by vaccinations lasts only a few years, he advises systematic revaccination of the population.

Should small-pox become widespread, an increase in the virulence of the disease may be expected, with a change from mild to severe forms of the disease.

In 1917 there was a limited epidemic of small-pox in Maine. Stimulated by this warning, the Boston health authorities in 1917 and 1918 were successful in obtaining the vaccination of fifty thousand of its citizens. Boston still has an unusually large unvaccinated population, a matter of much concern to its health guardians.

It will also be recalled that small-pox broke out among employees of the Goodyear Tire and Rubber Company, Akron, O., in 1917. Two cases developed in September, 1917, ten in October, and thirty-two in November. A survey of the fifteen thousand employees was made; of these, ten thousand had been previously vaccinated and showed good scars; of the remaining five thousand, 1,647 were vaccinated in the factory, with 1,415 successful vaccinations. Since then a rule has been put in force requiring the vaccination of all employees without good vaccination scars. This rule, in view of all the facts, might well be put in force by all employers of labor. Industrial plants are like schools in that they are places where large numbers of people come in close contact and thus facilitate the rapid spread of any contagious disease.

Not Confined to America

Dr. R. Wurtz,[2] professor in the Paris School of Medicine, has had occasion to call attention to the danger of small-pox in France and, more particularly, in Paris. The situation in 1919 was worse than at any time during the war, when people from all over the world were crowding into Paris. By referring to the records it was found that in 1914 only six cases developed in Paris; in 1915, seven cases; 1916, four cases; 1917, six cases; 1918, 55 cases; while in 1919, 47 cases developed during the first five months, with fifteen of these in April and twenty-two cases in May. Vigorous action was taken which tended to reduce the incidence. The reappearance of small-pox in France is ascribed to foreign importations from Morocco, Spain, Italy, and Algeria, together with violation of the sanitary regulations, especially in crossing from Northern Africa into France, and the obstinate refusal of the public to be vaccinated. He reported that more than 60 per cent of hospital patients had refused revaccination on the ground that they had been vaccinated in childhood.

Sir George Newman,[3] chief medical officer to the late Local Government Board, which has since been merged with the Ministry of Health of Great Britain, referred to the numerous outbreaks of small-pox in his report. For 1907, 206 cases were reported from fifty-eight sanitary districts. He notes that the percentage of children successfully vaccinated in 1917 was only 43.3 per cent, with exemptions of 37.9 per cent. He compares these figures with those of 1896, twenty years ago, when 61 per cent of the children were successfully vaccinated, with exemptions of only 5 per cent. Following the last serious epidemic of 1901 to 1904, 70 per cent of the children were successfully vaccinated. On account of the war the percentage of revaccinated men of ages twenty to forty is very large. This favorable situation as regards the adult male population is contrasted with the unprotected state as regards children. Col. J. W. S. McCullough,[4] Toronto, made similar observations, reporting 600,000 vaccinations in the Canadian Army with no untoward results.

When the public can purchase protection so cheaply by vaccination and revaccination, especially in view of the ravages of the past, one wonders at its gross general indifference. Boston has forgotten its epidemic of 1901

4. McCullough, Col. J. W. S.: Special Smallpox Bulletin of Chief Health Officer, Province of Ontario, Can., 1919.

and 1902, with its 1,528 cases and 190 deaths. In the eighteenth century small-pox was more common than measles. The Chinese long classed it as a children's disease. In 1802, a speaker in the British Parliament said that 45,000 died annually of small-pox in the United Kingdom. In 1702, 14.4 per cent of the population of the United States died of small-pox. In 1721, 5,989 out of a population of 16,000 in Boston succumbed to small-pox. In 1730, there were 4,000 cases of small-pox in Boston, with 500 deaths.

According to the China Medical Journal,[5] the innoculation of human beings with variola virus has been a recognized medical practice in China since the Sung dynasty in 1022. It seems that the Prime Minister, Wang Tan, had several sons who contracted small-pox. He heard of successful preventive innoculation practised by a Szechwanese living in the Ngo Wei Mountain. Wang Tan had a son innoculated and the innoculation proved successful. Following the publicity given the procedure by Wang Tan, the method was rapidly taken up and became popular with the people.

Researches in Variola

While considering small-pox, it may be interesting to call attention to some of the more recent researches. Sobernheim[6] notes fine granules, corresponding to Guarnieri's cell inclusions, which he thinks may be of etiological significance. These granules were found in the cornea of rabbits inoculated with pustule contents according to the method of Paul. The scarified cornea, rubbed with small-pox material, showed a macular reaction in thirty-six hours. When the eyeball was immersed in mercurous-chlorid-alcohol solution, the cornea turned grey, while the swellings showed as chalky white masses.

Casagrande, and later Knoepfelmacher, passed virus through a Chamberland candle and used the filtrate for subcutaneous injection. Using such a filtrate, Kraus and Volk[7] reported the hypodermic vaccination of one thousand cases by this method. Goodall[8] has recently reported very favorable results using similar technic, in the hypodermic injection of six thousand soldiers and children throughout a four-year period. This mode of vaccination against small-pox, according to Goddall, has the following points in its favor: (1) It leaves no open wound subject to infection. (2) It requires no dressing. (3) It produces a high percentage of "takes." (4) It is without severe local or general reactions. (5) It is a rapid means of vaccinating large numbers of patients. Chauveau (1886-1887) first proposed this method.

Hata[9] has reported on the use of autogenous serum in the therapy of small-pox. Dividing his cases into non-hemorrhagic and hemorrhagic types, he reports no deaths among the non-hemorrhagic cases treated with autogenous serum and a mortality 16 per cent less than those treated symptomatically among the hemorrhagic cases. Combining all cases, the mortality was 8.6 per cent less than with ordinary treatment. He also reports that the course of the disease was shortened. Normal human serum seemed to have no effect in small-pox.

THE MODERN FACTORY*

The importance of health conditions in the factory is indicated by the enumeration in the 1909 census of 6,615,046 persons in industrial establishments.

The opening chapters of "The Modern Factory," by George M. Price, give a cursory survey of the development of industry from the phase of the guild, employing few wage-workers, which contemplated turning out each worker a master of his craft, and in which the employers commingled with the workmen and were busy with the same tasks.

The shops where the medieval craftsman labored were usually small and dark; no sanitation was undertaken and "it is no wonder that the ranks of the workers of the middle ages were frequently decimated by plagues." Some records remain of an awakening sense on the part of some physicians and surgeons to the importance of health and sanitation, but it was not till the end of the sixteenth century that knowledge of industrial diseases and occupational influences became crystalized in the great work of the father of industrial hygiene, Barnardino Ramaggini.

The introduction of machinery, necessitating the concentration of capital, the construction of large factories, and the congregation in small areas of large numbers of workers produced economic causes of unrest which were at the root of all the English wars during the latter part of the eighteenth century.

Perhaps the greatest evil which followed the inception of the modern factory system was the "terrible exploitation of child labor in factories."

Out of the abuses at the beginning of the present industrial system have been evolved more intelligent attention to industrial problems and an appreciation of the facts that (1) the mortality of people living in industrial districts is much greater than that of persons living in agricultural districts; (2) the mortality of persons in certain general occupations, such as farmers, fishermen, or clergymen, is much lower in comparison to the mortality of persons pursuing industrial occupations; and (3) the mortality of persons in certain occupations is much lower than the mortality of persons who pursue occupations which contain elements of danger, and are of unhealthful character for one or more reasons.

With these premises admitted, the work place is considered as to its location, surroundings, and construction, and as to its internal arrangement. Impetus has been afforded by the fact that the highest standards of "model" factories have made for industrial efficiency, and for better relations between employees and employers.

"As progress is made in industrial conditions, and as the relation of sanitary science to industrial efficiency comes to be more generally understood, the conception of a model industrial establishment advances, and the state and municipal provisions constantly change and progress; so that what is today considered a voluntary provision by enlightened manufacturers becomes tomorrow the minimum provision required by the state."

From these general considerations chapters are developed on factory fires and their prevention, factory accidents and safety, illumination, sanitation, ventilation, welfare work, and the special hazards of the dusty trades and of industrial poisons, gases, and fumes.

The growth and tendencies in factory legislation lead to a discussion of the enforcement of such laws and to systematic inspection of factories. The treatment of these matters is necessarily brief but are specific and helpful, and have weight as the crystallization of the experience of the author's years of service as sanitary inspector of the New York Health Department and of his years of practice and of research into the sanitary sciences.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

MISS ALICE FITZGERALD, OF THE LEAGUE OF RED CROSS SOCIETIES

IN presenting the picture of Miss Alice Fitzgerald, chief of the Division of Nursing of the General Medical Department of the League of Red Cross Societies, Geneva, Switzerland, we cannot refrain from filling in some of the interesting details of her service during the war. Miss Fitzgerald was graduated from Johns Hopkins Hospital and had filled several important executive positions before she was sent to Europe in February, 1916, as the Edith Cavell Memorial Nurse, supported by a committee of loyal Bostonians.

Miss Fitzgerald's first service was under the auspices of the British organization that is known as the Q. A. I. M. N. S. R. (Queen Alexandra Imperial Military Nursing Service Reserve. (She was enrolled as a Sister (head nurse) and was sent first to Boulogne to a base hospital of seven hundred beds, where she had charge of a surgical ward. The hospital itself was of interest, as it was a casino transformed to meet the needs of the soldiers. Her work with the English nurses held a rather curious interest at first, as there were many differences of methods and practice, and even of terms. The work was fundamentally the same as that in American service, however, and she expresses herself as having found all of the British hospitals marvelously well conducted, the management and system providing for every contingency. Much of the dressing in the big surgical cases was left to the nurses, and in every instance in her experience everything that could be secured to make the men more comfortable was provided. Even on the front lines the system provided for the wounded men the daily rations of tobacco, and the afternoon cup of tea to which they had been accustomed. It was a part of the duty of the nurses to send twice a day bulletins on the condition of the seriously wounded men, so that the relatives of the men in Australia, Canada, South Africa, or any part of the world received authentic word of their condition and progress.

Her next work was in a barracks hospital near Bethune, where many trench fever cases were handled. Later she was sent to Italy to open hospitals and asylums for the refugees from the devastated regions. She served in one hospital on the road to Amiens which was shelled very often. It was later found that the Germans spared the hospital because it served their aviators, who made a sharp turn at that point, and its destruction would have hampered their movements. This was not known in time to save the disquiet caused by the proximity of the war machinery.

On her return to France Miss Fitzgerald was placed in charge of the American Red Cross nurses of the *Service de Santé*, her duty being to assign nurses to the French hospitals which were caring for American soldiers. These nurses were organized in teams of one American nurse and one aide who acted as interpreter in looking up lost American soldiers. In this way aid was extended to about four thousand soldiers. Her work took her all over France.

In May, 1919, she was appointed chief nurse of all the American Red Cross nurses in Europe, with headquarters in Paris, and in November, 1919, she received the appointment to her present position. In addition to her fine professional training and experience she is an accomplished linguist, speaking French, Italian, German, and English.

At present Miss Fitzgerald is arranging for a course in public health nursing in connection with King's College of the University of London, which the League of Red Crosses is offering to scholarship students from all of

Miss Alice Fitzgerald, chief of the Division of Nursing of the General Medical Department of the League of Red Cross Societies, Geneva, Switzerland.

the Red Cross societies represented in the League. A more interesting group of workers and a course more impregnated with great possibilities for the future international health would be hard to imagine.

Miss Fitzgerald was decorated by the Italian Government and by the British Red Cross for her services during the war.

A WARNING TO EMPLOYERS OF INDUSTRIAL NURSES

A WARNING has recently been sent to employers of industrial nurses in the state of Rhode Island by the secretary of the State Board of Health in the form of a bulletin which reads as follows:

It has recently come to our attention that certain nurses in the employ of manufacturing establishments in this state are, either by voluntary act or by the requirements of their employers, in effect violating the Medical Practice Act.

The State Board of Health is also the State Board of Registration in Medicine, and is therefore responsible for the strict compliance with the law on this subject.

The Board, at its regular meeting held May 13, 1920, voted to instruct the Secretary to write and send the following letter to all known employers of industrial nurses in the state:

A nurse or "First Aid" man or woman is permitted to render any "First Aid" service possible in the event of accident or disaster in case a physician is not available and until such time as one is available.

A nurse is allowed under these conditions to apply dressings or tourniquette or do anything else that in her opinion will be of service to the injured, or as an emergency measure.

She cannot, however, legally re-dress such wounds or combine treatment of the injured party except under the direction of a licensed physician.

The diagnosis of disease or the administration of drugs and the application of surgical dressing to wounded or injured parts except by duly licensed physicians is in violation of Chapter 193, General Laws of Rhode Island.

I also give below a definition of the practice of medicine given by our Supreme Court:

"Medicine, in the popular sense, is a remedial substance. The practice of medicine, as ordinarily or popularly understood, has relation to the art of preventing, curing, or alleviating disease or pain. It rests largely in the sciences of anatemy, physiology, and hygiene; it requires a knowledge of disease, its origin, its anatomical and physiological features, and its causative relation; and further, it requires a knowledge of drugs, their preparation and action. Popularly, it consists in the discovery of the cause and nature of disease, and the administration of remedies or the prescribing of treatment therefor."

This bulletin was sent over the official signature of B. U. Richards, M.D., secretary, Rhode Island State Board of Health, under date of May 27, 1920.

The work of industrial nurses is naturally varied. Each plant and each industry is a separate problem requiring distinctive individual methods of solution. Industrial nursing has been of rapid and recent growth. Nevertheless, the ultimate standardization of methods, records, equipment, and restrictions will soon evolve and will result in greater efficiency and safety, both to nurses and employees.

The bulletin is rightly addressed to the employers of industrial nurses, and not to the nurses themselves. The industrial nurse is an agent of the employer, and in no two places are her duties and responsibilities the same. Her service is often curtailed or misdirected because her employer has little idea what a well trained nurse can do for his industry, employees, and the community. For other employers her scope of activities is broad; and many industrial nurses find the giving of "first aid" in the factory only a small part of their most valuable service. They are doing sanitary inspection, accident prevention work, visiting nursing, and the caring for the sick in their homes, teaching the lessons of right living, prevention of disease, and elementary nursing principles in homes, factories, and schools. They supervise lunch rooms, rest rooms, and recreation centers. They make Americans out of foreigners.

Industrial nurses are public health nurses, and one of the most fundamental principles of public health nursing is that a doctor shall be in attendance on every case cared for; that the cases shall belong professionally to the doctor, not to the nurse; and that the nurse shall never take upon herself duties or responsibilities rightly belonging to the physician.

There is no reason why industrial nurses should carry any responsibility not usually assumed by other public health nurses. The leaders of industrial nursing have consistently stood for the employment of factory physicians and for the use of standing orders. Miss Florence Wright, chairman of the Industrial Nursing Section of the National Organization for Public Health Nursing, and author of the book, "Industrial Nursing," in a recent letter said: "I see nothing in the notice sent by the Rhode Island Department of Health to the industrial nurses which would be any handicap to their usefulness. We have from the beginning stood firmly on the ground that a company employing a nurse must employ a full- or part-time physician. Standing orders of such a physician would certainly constitute the 'direction of a licensed physician.' We have also stood firmly on the ground that a nurse should not administer drugs."

Most graduate nurses realize that industrial nursing is in a creative period, and the present-day industrial nurses have the power to create and build standards and prove that they are an indispensable part of a system designed to provide better health for industrial workers. Nevertheless, these nurses are constantly forced to realize that their work is being greatly retarded by the employment by many firms of untrained women. Miss Edna L. Foley, superintendent of the Visiting Nurse Association of Chicago, says:

I was very much interested in the statement issued by the State Board of Health of Rhode Island, for I have wondered how long it would be before some enterprising physicians caused such a statement to be given.

Several years ago some of us thought that factories were putting in industrial nurses in order to save the salaries of physicians. Many of these nurses were but half trained people who were more than willing to trust themselves to do a great deal. A well trained nurse will rarely, if ever, allow herself to do daily dressings, without a doctor's orders, or to prescribe medicine; but a badly trained nurse is always so deadly confident that she rarely gets a case that she is afraid to handle. I have known of aspirin given to heart cases because the so-called "industrial nurse" thought the symptoms were those of grippe, and I have seen cathartics, aromatic spirits, and headache tablets given as freely as water by equally incompetent assistants.

A good nurse knows that she is not licensed to practise medicine and she doesn't attempt it; but I once knew of a school nurse who was almost dismissed by the President of the Board of Education because she refused to treat the children in a large public school without the sanction of the local medical society, since the town felt it was too poor to pay a medical inspector. All sorts of unfair pressure is brought to bear upon women who are themselves not too well trained and, consequently, they do more than first aid and perhaps they are fairly often guilty of actually practising medicine. Ignorance of law or personal innocence is really no excuse.

An industrial nurse who has her wits about her can almost always make her firm see that it will be better and less expensive in the long run for them to call in a local physician and make such arrangements with him that

she may call him in an emergency or send special cases to him. If this physician is put in the employ of the company and is somewhat familiar with conditions of work, he is usually more than willing to give the nurse a few helpful and more or less simple p. r. n. orders. If these orders may not be repeated more than once for the same person without special reference of that case to the physician, it will prevent a nurse from falling into the habit of giving C.C. or migrain tablets too carelessly, which I once saw done in the medical department of a firm employing four doctors and several nurses. When we made the rule that no patient could have a p. r. n. dose more than once without seeing the doctor, the amount of requests for p. r. n. dropped one-half and the girls seemed none the worse off for it.

A good nurse, whether she is working in a public school or in a factory, does not like to feel that she may not, at a moment's notice, consult a physician if she needs to, and we will only help standardize industrial nursing when we recognize this fact and persuade employers to be just as careful in the selection of part-time or full-time physicians for their people as they should be in their selection of nurses.

Miss Foley, as usual, hit the nail on the head in saying that well trained nurses rarely usurp the duties or responsibilities of the physician.

A letter from Miss Mary S. Gardner, superintendent of the Providence, R. I., District Nurses' Association, and author of the book "Public Health Nursing," corroborates our belief by saying:

I have taken a day or two to get a little more information from one of the prominent industrial nurses here in regard to Dr. Richard's bulletin. She tells me that before the bulletin came out he gathered the industrial nurses of the state together and talked things over with them. The situation in Rhode Island was pretty bad, for there were a number of women *who were not graduate nurses doing industrial nursing and taking astonishing liberties in regard to prescribing medicine, diagnosing cases, and giving treatment.*

As far as I can discover, the well trained industrial nurses feel that the bulletin is a good thing wherever the regular doctor is in attendance or wherever standing orders can be obtained; but that occasionally it is limiting not to be able to prescribe a cathartic or some other similar thing, but all feel that too much curtailment is better than too great liberty.

While trying to place the blame where it belongs for a condition existing not alone in one state but in all where industrial nurses are being employed, we must not neglect the fact that many nurses young and new in the work are not properly directed by the plant physician. Miss Janet Geister, secretary of the National Organization for Public Health Nursing, says:

Many times industrial physicians are too willing to relegate important functions to the industrial nurse; and the nurse, often new and poorly trained, foolishly accepts these responsibilities. I remember when I was supervising industrial nurses in Chicago, one of the first nurses that I interviewed was doing much first aid work that she had no right to do. She rebelled against my suggestion that she take care of only minor injuries, and *the doctor for the plant encouraged her in protesting against my recommendation.* We succeeded, however, in bringing about a satisfactory arrangement. I do not think we can too strongly urge the need for well defined, carefully worked out standing orders that would receive the approval of medical men in general and not merely be the instruction of the physician in the plant. It is, of course, not necessary to get the endorsement of all local medical men, but it is highly important for the nurse to be certain that in carrying out her standing orders she is not violating the laws of her state, and she should always limit her dressings to those that are permitted under her standing orders.

We must not fail, while discussing this industrial nurse situation, for the sake of future industrial nursing, to express the earnest hope that the bulletin will serve as a drastic warning to those nurses who may be well trained but careless, and to those poorly trained and ignorant of the fact that leading nurses, with knowledge and vision, and nursing organizations, do not sponsor or approve of nurses who, either by their own voluntary act or through the requirements of their employers, in any way violate the Medical Practice Act.

These nurses retard seriously the growth and development of industrial nursing, and at the same time place themselves in danger of legal prosecution. EDITOR.

SICK BABIES GO A-SAILING ABOARD A FLOATING HOSPITAL

Past the docks in the New York Harbor each day and each night there sails a floating hospital carrying on board toward the mouth of the harbor into the cool sea breezes several hundred sick babies and their mothers. Down it sails with its patients, the babies from New York and Brooklyn dwellings who have been sought out from the crowded districts, from hot, sweltering tenement buildings, and from the homes of poor families who are unable to give the baby such nursing and medical care as it should receive.

The St. John's Guild operates the hospital. Since 1873 the Guild has maintained a boat for the care of babies and mothers, and hospital service has been a feature of the enterprise since 1887. The craft now in operation is known as the Helen C. Juilliard Floating Hospital. It was so named after the late Mrs. Augustus D. Juilliard, one of the principal donors of the second and third hospital ships which the St. John's Guild has built in the last score of years.

The boat leaves three piers in New York on three days of each week and on other days it leaves from three Brooklyn piers. The day trips are for sick and ailing children under six years of age. Their mothers may accompany them on the day trips, but not at night. Both mother and child are in need of medical attention in numbers of cases. Contagious diseases are not accepted, but any other case of illness or serious sickness will be admitted after examination by a physician. The babies are located by visits to dispensaries, hospitals, milk stations, settlement houses, and other community gathering places.

In conjunction with the floating hospital the St. John's Guild conducts the Seaside Hospital, which is situated on the shore at New Dorp, on Staten Island, just across the lower bay from Sandy Hook. The beach at Seaside furnishes an excellent playground for the little ones. The children bathe here too. The water near the hospital for several hundred feet is shallow and well suited for the children's use.

The hospital staff of the Helen C. Juilliard includes two physicians, a dentist, a superintendent of nurses, a matron, and six nurses. Nine other nurses are at all times making visits in various districts of New York and Brooklyn searching out the families who have sick and ailing babies or small children. If a case requires a longer period of treatment than can be given aboard the Helen C. Juilliard, the child is transferred to the Seaside Hospital.

The boat now in use was built in 1916. It has four wards on the front upper deck of the vessel. Another small ward is provided for the care of mothers if occasion arises. Complete facilities are provided for ward service, nursing, and for operations. Hot and cold baths are accessible to mothers and children. These are provided with either fresh water or salt water. The children are bathed on a drain board or bathing table, near which are situated small tubs. After having its bath on

The Helen C. Juilliard Floating Hospital.

the drain board, the baby is dipped in the tub. Clean clothes which have been placed in a warmer are waiting for each child after its bath.

The boat has sterilizing apparatus and all other equipment necessary to make it an ideal hospital of its kind. There is a small mortuary, but deaths occur infrequently, although no cases of sickness are ever refused, excepting contagious diseases.

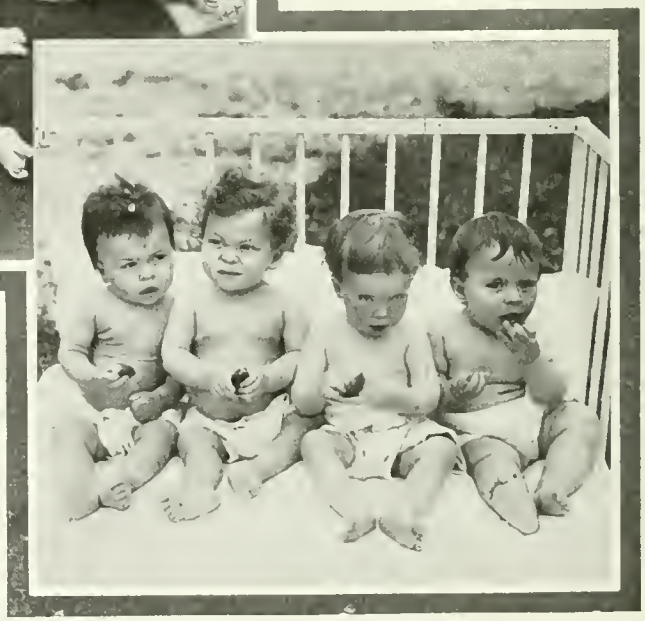
The first trip on the Helen C. Juilliard.

A diet kitchen under charge of a competent dietitian supplies meals. Everything is free, but on the day trips the mothers are asked to bring a clean pitcher or a tin pail for milk, and to carry along warm wraps for the children. Adults receive a large noon meal and two meals are served each day for the children on every trip, which consumes practically the entire day.

The boat is 215 feet over all in length, with a beam of 43 feet. It has a legal carrying capacity of 2,400, but the number has been limited to 1,200 to provide for better service. It was built and equipped at a cost of $125,000, which was donated by Mrs. Juilliard, who died only a short while before the new ship was complete for service. It has electric light and steam heating plants, which can be used in winter as well as summer if found necessary.

Babies who are not so sick that they need to be placed in one of the wards, if with their mothers, are kept on one of the decks, where benches are provided for the mothers with a convenient arrangement of hammocks swung on iron frames attached to the backs of the benches, in which the babies are placed.

The work of the hospital staff does not end with caring for the sick children and mothers, however. Instruction for mothers in how to prevent sickness in their



Seasoned voyagers on the Floating Hospital.

Mothers sit on the benches, with their babies beside them in hammocks.

families is one of the regular activities of the physicians and nurses.

The plan of taking mothers and children on the trips has been adopted because in this way it is easier to gain the consent of the parents to allowing their babies to be taken on the hospital ship. The instruction which mothers receive at the same time compensates for the extra effort in providing for their comfort and care.

At the Seaside Hospital the patients are kept as long as the attending physicians believe necessary and no time limit is fixed. If the child should be taken seriously ill, the parents are immediately notified by telephone or telegraph, and they can come at any hour, day or night; otherwise the regular visiting day is Sunday.

The operating cases are few, but the Seaside Hospital is thoroughly equipped for any emergency. A large supply of sterilized dressings, instruments, etc., is always on hand.

Considerable laboratory work is done at Seaside, for which there is a complete equipment. There is also a fully equipped dental office, in which the teeth of children are put in good repair. Caring for the children's teeth is a feature of the work; the older ones are taught and made to take proper care of their teeth, as are also mothers who remain with the children.

HEALTH STATISTICS FROM BELGIUM

Vital statistics in Belgium brought together recently afford an interesting picture of the effects of the war. In general the mortality curves show four or five times the normal number of deaths between 1913 and 1918, the maximum being six times the normal rate during 1917. While the birth rate was lower than normal, the infant mortality rate was diminished. In the Brussels district the typhoid rate diminished to half or less, but tuberculosis and heart disease doubled. Senile debility doubled. Cancer increased steadily as a cause of death. With the exception of the social diseases, death from communicable diseases decreased.

AN EQUAL CHANCE

WHAT is a public health nurse? Whom does she serve and how? Why is she "one of society's indispensables"? When these questions are asked, answer them with pictures. The National Organization for Public Health Nursing has recently completed a film portraying public health nursing in cities, rural, and small town districts.

The "story" part of the film was taken in Duchess County, New York, with the cooperation of the New York State Department of Health. Other pictures were taken on the Wind River Reservation in Wyoming, in Chicago, in St. Mary's Parish, Louisiana, and in the village of Isleta, N. M. All details of nursing technic have been carefully supervised by competent censors. The following associations have recently bought copies of the film, so that it will be available to communities within their district: The National Tuberculosis Association, 381 Fourth Avenue, New York City; the Community Motion Picture Bureau, 46 West Twenty-fourth Street, New York City; American Red Cross Bureau of Motion Pictures, 44 East Twenty-third Street, New York City; New York State Department of Health, Springfield, Ill.; the Boston Instructive District Nursing Association, 561 Massachusetts Avenue, Boston, Mass.; Connecticut State Department of Health, Austin, Tex.; Kansas State Department of Health, Topeka, Kan.; Southwestern Division, American Red Cross, Equitable Building, St. Louis, Mo.; Southern Division, American Red Cross, 249 Ivy Street, Atlanta, Ga.; Pacific Division, American Red Cross, 864 Mission Street, San Francisco, Cal.; Gulf Division, American Red Cross, Washington Artillery Hall, New Orleans, La.; and Central Division, American Red Cross, Pioneer Building, South Water Street, Chicago, Ill.

The Film Tells a Story

When the influenza epidemic swept the country in the fall of 1918, Shirleyville Township found itself with no public health nurse and only one doctor, the others having been called away for military service. The overworked physician applied to the nursing association in the neighboring city for a public health nurse to aid him in caring for the stricken district. The nursing association is obliged to refuse at first, but at length when it becomes possible to assign a nurse for duty in Shirleyville, the rich farmer of the district, misunderstanding the relation of the public health nurse to the community which she serves, attempts to appropriate her services exclusively for the care of his sick child. Miss Gillis, the public health nurse, points out that there are other families in the district who must be given an equal chance in the emergency. Later, Reynolds, the rich farmer, is completely won over by Miss Gillis' success not only as an efficient aid to the doctor in bedside nursing, but as a teacher of the principles of sickness-prevention.

A Film Within A Film

In the country school, as a result of her efforts, the children are taught health habits and are given regular examinations by a doctor. Shirleyville discovers that in the public health nurse it has acquired a public servant who is well nigh indispensable, not only in an emergency like the epidemic, but in the everyday work and play of the community. So Reynolds, who has become an enthusiastic convert, induces the state health department to send the Healthmobile to Shirleyville and calls a mass meeting to decide whether Shirleyville wishes to retain its public health nurse permanently. In the course of the meeting

Even the "Movie Man" is enlisted in the general campaign for health. He brings this picture record of the visiting nurse service to the tepee tents of the Pueblos at Isleta, N. M., and to the Arapahoes and Shoshones in Wyoming.

Interest in health matters is registered in the picaninny faces from the Southland. Chief Yellow Calf thanks the movie man for his services, and good Indians everywhere show themselves ready to co-operate.

the Healthmobile shows motion pictures—a "film within a film"—demonstrating the work of the public health nurse in open air schools for tuberculous children, among the Shoshone and Arapahoe Indians on the Wind River reservation in Wyoming, and among the negroes in the semi-tropical scenery of Louisiana. Reynolds then puts the question, "Do we want to keep the Public Health Nurse"? and the meeting votes "Yes" by acclamation.

Besides the demonstrations of bedside care, home instruction, and country school nursing which are woven into the body of the story, the "Film within a film" makes it possible to include accurate representations of various other branches of public health nursing, such as maternity care, infant welfare, and tuberculosis, without breaking the thread of the narrative. The interesting story of health work "gets across" in this dramatic presentation.

HEALTH WORK AT THE COUNTY FAIR

By MISS STELLA FULLER, Extension Secretary, Central Branch Office, National Organization for Public Health Nursing, Chicago, Ill.

COUNTY fairs are not original with us; they are held in practically every civilized land. The peasants of Europe bring their stock and their produce to the villages and towns at regular times. It is natural to visit and play a bit whenever a large group of people get together.

To those of us who were born and bred in the country the thought of "fair week" is filled with happy meaning. The long years that have passed between have not effaced the memory of those delightful days when dressed in our best clothes we piled into the lumber wagon with Pa and Ma, and drove off to the County Seat to the Fair.

All along the way, we greeted our neighbors and friends bound for the "grounds." Life held nothing so dear as a ride on the Merry-go-round, a chance to carry a brightly colored balloon, a dime to shoot at the "nigger babies," a look at the races, and a visit to the stock barns and the exhibition rooms. Wasn't it hard to wait until dinner time when Mother spread the picnic lunch under the trees, with sandwiches, cake, fruit, and *maybe* a little roasted pig.

At the end of a perfect day, we drove home, our money spent, our best clothes soiled, almost too tired to do the chores, but blissfully happy and wishing we could go again the next day.

The Fair Gains in Influence

The County Fair has lost none of its charm, but it has gained considerably in its influence on country life in the

"An Equal Chance for All" is extended to these babies, who are being cared for by the Chicago Infant Welfare Association.

past ten years. The country people themselves, the women's clubs, the rural school teachers, the county demonstration agents, and the public health nurses have wrought the change. *Now*, no County Fair is considered a success if it does not include something that emphasizes healthy parents and healthy children, as well as healthy *live stock*.

It is a common thing now to have a rest tent where tired mothers may come to nurse their babies and to leave

This "Health Tent" maintained by the American Red Cross at the county fair is wholly constructive in its influence, emphasizing, as it does, the importance of healthy parents and healthy children.

them in dainty cots to be cared for by the County Nurse and her assistants. The mothers like to know there is a place where they can "wash up" and get away from the crowd a bit, a place where they can talk to the nurse about the health of their children, and perhaps have the babies weighed, measured, and registered.

Some of the nurses have an extra tent or room for this work. Through the cooperation of local physicians they have physical examinations of old and young and give out health literature to those who care to have it.

Nurses who make the most success in this work are the ones who conduct an extensive publicity campaign at least one month before the fair, and who interest their committees, their friends, and their neighbors in giving time and help to this important part of the harvest gathering.

The health exhibit giving information on proper diets, sanitation, ventilation, and right health habits is now quite as interesting and more worth while than the crocheted bed spreads and the prize roosters.

Health Interests Everybody

In competition with the old time side show where the fat lady and the living skeleton sat on decorated thrones, there are splendid health moving picture shows or lantern slides with lectures that teach the value of good health to old and young. Where the professional barker stood at the tent door and extolled the mysteries of hidden entertainers and grew eloquent of the splendid exhibition within, the Camp Fire Girls, the Boy Scouts, and the Modern Health Crusaders may give health plays or dialogues demonstrating the value of boys and girls clubs in the health and economic growth of the nation.

In the old fair days the kiddies, and their parents, too, were amused at the antics of clowns who performed on platforms twice during the day. The very latest evolution of "clowndom" is the health clown who goes about through the fair grounds carrying health banners, waving health signs, brandishing tooth brushes, his pockets bulging with vegetables and other foods that prevent and cure malnutrition. He knows little health rhymes and jingles that he recites or sings. He jokes the people, young and old, peering into their faces to see whether their cheeks are red and their teeth are clean. He lifts tiny boys and girls to see whether they weigh as much as they should, and, altogether, through the whole day, this health knight continues to suggest *health* to the great crowds that throng the park and choke the grandstand. The small amount of money it is necessary to pay him comes back eventually in better, stronger men and women.

Sometimes, in competition with the parades of breeded stock, sleek and well fed, he organizes a parade of healthy boys and girls, pushing aside with pitying hand those who do not measure up to his ideas of what health means. Cho Cho, a professional Health Clown, may be secured from the Child Health Organization 156 Fifth Avenue, New York City, if his services are requested early.

A Self-Service Bath Room

One county nurse showed a facsimile of a bath room she had arranged in a farm house where there was no running water.

It is like the Blank's, she said. I had visited the home for several days when the youngest baby was born and later when Jimmy broke his arm. The poor lad was sadly in need of a bath; so, while Mrs. Blank finished her washing, I gave the little chap the best scrubbing he had received since swimming time last summer. His tired mother was pleased as could be and said she wanted her family to bathe every Saturday, but there was no bath room and well—she couldn't make them do it.

To make a long story short, within a week the Blanks had a comfortable place to bathe. A small room off the kitchen was emptied, cleaned, painted, and fitted up with small stove, rag rugs, sash curtains, two chairs, a cupboard for towels, wash cloths, under clothing and night clothes, a covered laundry basket, a mirror, first aid cabinet, a shelf for manicure set, shaving outfit, tooth brushes, paste and dental floss, box for clothes brushes and shoe polish, water pail, wash tub, waste pail, foot tub, hot water bags, and fountain syringe.

As a last touch, I added a health sign or two and voila—the Blanks now are *clean* and there are no quarrels on Saturday night.

This nurse is just one of thousands of health missionaries who will, during the months of August and September, do many things in connection with the county fairs to promote health and happiness on the farm and incidentally help to keep the boys and girls from flocking to the over crowded cities where the pay may be more, but the opportunities for a peaceful, happy life, much less.

The organization* of this work provides: (1) *publicity through* schools, churches, committees, fair board, and newspapers; (2) *rest tent for* mothers, babies, distribution of literature, and individual conferences; (3) *a health tent for* registration of children and adults, weighing and measuring, physical examinations, children, and adults; health talks, health slides and moving pictures, exhibits and contests (school children participating). Camp Fire ceremonials, Boy Scouts, to assist with *first aid*, and demonstrations by nurses; (4) *a health clown to* carry health banners, recite health rhymes, organize health games and parade, distribute health literature, and emphasize health in various ways; and (5) *a model farm bath room containing* sash curtains, rag rugs, two chairs, cupboards, shelves, small stove and tea kettle or wash boiler, laundry basket, waste paper basket, first aid cabinet, fountain syringe and hot water bags, mirror, toilet necessities, water pail and waste pail, wash tub, foot tub, under clothing, and nightclothes.

*Further details may be secured by writing to the National Organization for Public Health Nursing, 116 S. Michigan Ave., Chicago, Ill.

HYCLORITE
REG. U.S. PAT. OFF.
CONCENTRATED SODIUM HYPOCHLORITE

Always Ready—No Time Lost

INDICATED in surgical dressing and treatment of wounds where there are large masses of dead and devitalized tissues or profuse tissue exudate which cannot be removed by mechanical means.

Hyclorite liberates its chlorine content promptly and in proportion to the degree of putrescence to be overcome. It rapidly oxidizes the toxins and dissolves the necrosed tissue.

In contrast to the irritating effects of the ordinary Dakin solution and chloramine antiseptics, Hyclorite is practically non-irritating.

Hyclorite is also uniform in hypochlorite strength, (Na OCL 4.05%) and of exceedingly low alkalinity. (¼ of 1%). It does not deteriorate appreciably with age.

It exerts a powerful, indirect germicidal action. Promotes rapid healing.

Makes a correct Dakin solution in one minute. Just add water. No testing necessary.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRITPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume 1, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

Current Literature and Book Reviews

A TEXT BOOK OF PHYSIOLOGY. For Students and Practitioners of Medicine. By Russell Burton-Opitz, S.M., M.D., Ph.D., associate professor of physiology, Columbia University.[1]

The author has succeeded in presenting the subject of physiology in as simple a manner as possible. The medical student of today is so overworked that he cannot afford to read long mathematical and chemical formulas, and any textbook that eases his burden will be welcomed by him.

As a whole the book is complete. Here and there, however, one notices certain omissions or disproportions. In the short article on the history of physiology on pages 18 and 19, the author left out so gigantic a name as Magendie. It is true that the author did not intend to write a history of physiology, yet he mentions some names that are less important than that of Magendie.

The subject of cerebrospinal fluid is dismissed by the author in half a page in one part, and a little over a page in another part of the book.

Cerebrospinal fluid certainly deserves much more consideration than a page and a half of space.

Urine is another subject that deserves greater attention in a textbook on physiology than is given to it by the author, especially since the medical student will have to refer constantly to the subject in his clinical study. The part dealing with the composition of urine is entirely too short for a modern physiology.

On the other hand, the section dealing with the mechanics of the heart is quite long, possibly out of proportion to other subjects. While we are aware of the fact that the author has done much research on the subject of circulation, the student does not like to read long treatises.

In general the book is easily and thoroughly written and deserves a place in the library of every physician.

THE HISTORICAL SOURCES OF DEFOE'S JOURNAL OF THE PLAGUE YEAR. By extracts from the original documents in the Burney collection and manuscript room in the British Museum. By Watson Nicholson, Ph.D.[2]

In these days of excitement, of new processes and new inventions, one seldom finds a person who is willing to give up his time to establish a historical fact or to correct a historical mistake. It is, therefore, gratifying to see the book of Dr. Nicholson, showing that Defoe's Journal of the plague, which has been considered mere fiction, is based on historical facts. The author spent a great deal of time at the British Museum, studying the records of the various plague epidemics in Great Britain. He claims to have established the historical accuracy of Defoe's Journal beyond doubt. The author should be commended for this hard but interesting historical research.

Actual Laboratory Conditions of Cleanliness Surround the Production of

HEBE

—the modern food discovery for Cooking and Baking

HEBE merits the interest of physicians, health officials, dietitians, public health and industrial nurses—those who are most concerned in community health and welfare. Scrupulous care is taken in the production of HEBE from the preliminary testing of dairy herds to the final sterilization of the product. Sanitary conditions safeguard every process, and the product reaches the consumer, pure and clean in hermetically sealed cans.

HEBE is a scientific emulsion of pure skimmed milk and refined cocoanut fat. These two highly nutritious natural foods in combination form a wholesome food product, rich in necessary dietary elements,—proteins, carbohydrates and fat.

HEBE contains all the solid constituents of the skimmed milk ***plus*** the heat and energy value of a scientifically processed vegetable fat. It is an economical, convenient and wholesome product, an ingredient in cooking, serving as an auxiliary to the daily milk supply.

HEBE is recognized not only as a healthful, easily digested food product, but also as an important addition to the human dietary. It reclaims for human food a part of the billions of pounds of skimmed milk which is ordinarily fed to live stock on the farm, thus adding materially to the food supply of the world.

HEBE is plainly labeled "A compound of Evaporated Skimmed Milk and Vegetable Fat." It is recommended as a liquid ingredient for cooked foods. It is not intended to replace milk for infant feeding.

The dietetic and economic importance of HEBE is of especial interest wherever a constant supply of pure, healthful food is a problem. We will gladly send upon request a booklet giving the complete facts about HEBE—Its Dietetic and Economic Value. Address 2822 Consumers Building, Chicago.

THE HEBE COMPANY

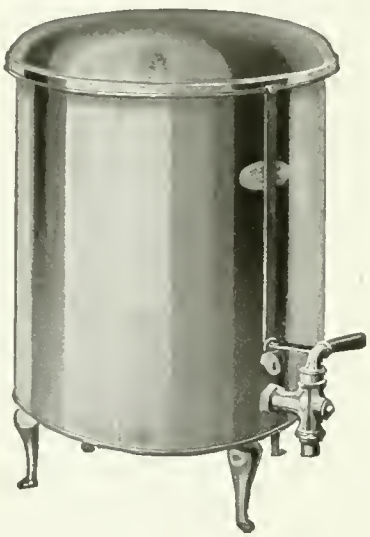
Lyons Sanitary Milk Urn

Butterfats and Sanitation Speed without Slop Nor Waste

Clean, Rich Milk

FOR YOUR PATIENTS AND EMPLOYEES



Another Striking Feature of the Lyons Urn is that the cover and faucet can be locked after each meal.

Dipping Milk is Sloppy
Bottled Milk is Costly

YOU know that the cream rises to the top of the milk, and with all other make urns the first ones get all the skim-milk from the bottom, while the last ones get what is left—all the cream.

Lyons Sanitary Milk Urn is the only urn that dispenses milk containing the proper percentage of cream in each and every glass served, without any mixing, stirring, or other agitating mechanism, and it makes no difference whether the milk remains in the urn 2 minutes or 24 hours. Place the day's supply of milk in the urn and draw it out through the faucet as you need it, and the milk will always be sweet, clean, cold and fresh.

Lyons Sanitary Urn Company

235 EAST 44TH ST. NEW YORK CITY

INTERNATIONAL SANITARY CONFERENCE

The Sixth International Sanitary Conference of the American Republics will be held in Montevideo, Uruguay, December 10 to 20, under the presidency of Dr. E. Fernandez Espiro and the auspices of the government of Uruguay.

A PAN-AMERICAN CONFERENCE

Plans have been laid for a Pan-American conference on control of venereal diseases, to be held at Washington, probably in December of this year.

The American Red Cross has taken an active part in making this conference possible. It has the cooperation of the United States Public Health Service, the United States Interdepartmental Social Hygiene Board, and the American Social Hygiene Association.

The work of the conference, which will probably bring many leading thinkers of Latin America to the United States, will deal with three groups of problems in the control of venereal diseases, namely, the purely scientific, the administrative, and those which have particular public interest.

CUBAN ANTIMALARIAL MEASURES

Health work in Cuba during the past twenty months, ending in August, 1919, is reported in a recent issue of the *Boston Transcript* as having included important measures against malaria. The provinces of Camaguey and Oriente were selected for the demonstration, the district being covered by special civilian sanitary police whose mission was to discover paludies. Houses of patients were furnished with mosquito netting and the patients treated at home, when possible. Owners of plantations were furnished with quinin for their laborers, and educational posters were used. Examination was made of the blood of school children. Canalization and the clearing of all grass and shrubs about streams were practised, and in the drainage operations the government was ready to furnish plans for the plantations. Petrolization was found a useful process during the dry season. This work in Cuba fits in with many similar enterprises in the southern part of the United States.

DECLINE IN SUICIDE RATES

The observation that war service deflects the morbid tendencies of people with introspective habits of mind was borne out by the report of the Registrar General for England and Wales, which showed a decline of the suicide rate of more than 25 per cent in 1915.

The experience among industrial policyholders in the United States reported by the Metropolitan Life Insurance Company is interesting in this connection, as they show a very definite downward tendency in the death rate for suicide in the period between 1916 and 1919. In 1916 the suicide rate for white males was 15.3 per 100,000; in 1919 the rate was under 10, representing a decline of 37 per cent in the three year period.

The change was less significant among colored policyholders. The facts for homicide, on the other hand, do not show any such effect of war conditions as were apparent for suicide. Colored lives show much higher rates, with extreme conditions among colored males. . . . Among colored males homicide ranks third as a cause of death in early adult life, being exceeded only by the incidence of tuberculosis and the acute respiratory diseases.—*Statistical Bulletin.*

What of the New Bed?

Shall it be selected as a mere piece of furniture, or shall we choose it with proper regard for its comfort and sleeping qualities?

A BETTER appreciation of the health-building functions of sleep has resulted in new and different buying ideas than those which formerly influenced the choice and purchase of a new bed.

Not so many years ago, when the demands for additional sleeping accommodations emphasized the need of it, most people, when the time came to buy a new bed, simply went to their favorite furniture store and "picked out" another bed

If the bed thus selected "matched up" with the other furniture of the room, so much the better. If its parts were hard to fit together, a "man from the store" came over and bolted it together. If, later, its parts became loose, or if the joints squeaked and rattled, or if its crevices harbored vermine, everybody did what they could and made the best of it. Having no standard of bed *value*, quality or service, no one could be very particular.

Now the bed-buying ideas in every family are more exacting. Instead of being satisfied with the old-fashioned wooden bed, its noise-disturbing faults and loose joints, or the old time "gas-pipe-like" metal beds of unsightly memory, people are more discriminating.

Instead of going to the store for "another new bed," judging its merits and selecting it finally, as a piece of furniture—buyers are more and more considering its comfort and sleep qualities above all else. If it measures up to the Simmons standard—they feel secure.

Simmons Beds, *"Built for Sleep"* cost no more than perfect beds ought to cost—no more than anybody who values comfort and health will be fully prepared to pay.

The quiet elegance, simplicity and refinement of Simmons beds, their superior construction and the certainty with which they encourage sleep, make them essential to the health, comfort and efficiency of the people.

Appetizing Foods with Nourishment and Flavor

When every day's diet counts for rapid recovery and where it is so hard to provide nourishing and wholesome foods that tempt the appetite of the convalescent—then is the time to appeal to the convalescent through flavor. Flavor stimulates a desire for food to which it is added, and helps the convalescent to take the proper nourishment necessary.

The uniformly high quality of

SAUER'S
PURE FLAVORING EXTRACTS

made from the choicest materials obtainable and where every possible care is taken in their manufacture is widely recognized by the hospitals in the United States.

Various American and European Expositions have awarded seventeen highest awards to Sauer's Extracts for Purity, Strength and Flavor.

Further Particulars free on request.

The C. F. Sauer Company

Richmond, Virginia

NATIONAL DENTAL ASSOCIATION MEETS

The Twenty-fourth Annual Session of the National Dental Association will be held August 23 to 27, 1920, in the Mechanics Building, Boston, Mass. The program is of great interest and the seminar course clinic provided constitutes what is practically a post-graduate course in every phase of modern dentistry.

SUBSIDIZES MEDICAL EDUCATION

The University of Virginia, at Charlottesville, has raised an emergency fund of $12,000 to make possible the admission of a large number of applicants to the freshman class in medicine at the next session. The sum of $2,400 subscribed by the medical faculty formed the nucleus of a fund which is now sufficient to avert the necessity of turning away desirable applicants for medical courses.

NATIONAL ANESTHESIA RESEARCH SOCIETY MEETS

The National Anesthesia Research Society will meet with the Interstate Association of Anesthetists, the Pennsylvania State Medical Association, and the Western Pennsylvania Odontological Society in Pittsburgh, October 4-7, 1920. This will be one of the largest and most important meetings ever held to advance the science and practice of anesthesia. To stimulate the presentation of worth-while papers on researches in anesthesia, the N. A. R. S. will award money prizes for the three best papers submitted on this occasion. All activities of the meeting will be centered in the William Penn and Fort Pitt hotels.

NINTH ANNUAL SAFETY CONGRESS

The tentative announcements of the program of the Ninth Annual Safety Congress, which will convene in Milwaukee, Wis., September 27 to October 1, 1920, make mention of the fact that 179 speakers will address the various sections on some particular phase of accident prevention or industrial health work. Among the speakers announced are:

Samuel O. Dunn, editor of the *Railway Age*, vice-president of the Simmons-Boardman Publishing Company, president of the Associated Business Papers, Inc., and one of the most prominent authorities on railroad transportation, who will address the Steam Railroad Section.

Dr. Harry E. Mock, of Rush Medical College, Chicago, author of "Industrial Medicine and Surgery," a work that has become generally recognized as the standard textbook of industrial medicine and surgery, who will speak before the Health Service Section.

James Newton Gunn, president of the United States Tire Company, who will address the Rubber Section.

C. H. Clark, editor of the *Textile World Journal*, who will address the Textile Section.

Dr. Otto B. Geier, president of the American Association of Industrial Physicians and Surgeons, and Dr. J. J. Moorehead, formerly Lieutenant Colonel, U. S. A., both of whom will deliver papers before the Health Service Section. Dr. Moorehead spent twenty-three months on the firing line in France and was awarded the Croix du Guerre by the French Government for conspicuous bravery.

C. H. Baltzell, superintendent of the St. Louis and San Francisco Railroad, also will address the Railroad Section.

Grape Ola

is a delicious natural food drink, exceptionally pleasing and beneficial to everyone, from little children to grandparents.

Because of its healthful qualities and easy assimilation it is an ideal drink for the sick, the convalescent, and for general hospital use.

Its rich, ruby-red color and delicious grape flavor give it an unusual appeal to the most delicate appetite.

Grape Ola is not only a more pleasing drink than the ordinary grape juice, but much more economical. Quickly and easily made by simply mixing 4 or 5 parts water with one part of

Grape Ola Concentrate

One quart makes 30 glasses—No sugar required

A sample of Grape Ola Concentrate sufficient to make 7 or 8 glasses of Grape Ola will be mailed to any physician on receipt of 25c to cover cost of mailing.

Fill out attached coupon and mail to

MENTAL HYGIENE STUDIED IN OREGON

A state-wide study of mental hygiene and dependency is being carried on in Oregon through the cooperation of the University of Oregon, the state health authorities, and the United States Public Health Service. This study was directed to be made by the Legislature in 1919. The work is under the direction of Dr. Chester L. Carlisle of the United States Public Health Service.

ASSOCIATION FOR MEDICAL EDUCATION

The work of the New York Association for Medical Education for the year was reviewed at a meeting held June 21, 1920. The work of the ensuing year will be in the hands of newly elected officers as follows: President, Dr. Haven Emerson; first vice-president, Dr. George David Stewart; second vice-president, Dr. Glentworth R. Butler; secretary, Dr. Otto V. Huffman; and treasurer, Dr. Arthur F. Chace. Dr. Wendell Phillips, the retiring president, was the founder and organizer of the Association.

THERAPEUTIC VALUE OF COLOR

Powerful curatives as well as mental sedatives are to be found in the use of properly selected colors, and in the right proportions, says Howard Kemp Prossor in the April issue of the *Medical Times*. Athletes find help in fixing their eyes on a red handkerchief before running a race. Scarlet rooms are beneficial for lazy boys, while blue at the other end of the spectrum is magnetic and soothing and helps concentration.

The fear created in men's minds by neurasthenia may be counteracted by using in the wards of such patients colors which generate strength and courage. Blue ceilings and yellow walls do away with the feeling of confinement between them. The combination of blue and violet has been found beneficial for insomnia. Headaches can be dealt with in blues, violets, mauves and greens.

Progress in the use of color therapeutics must be through a scientific knowledge of color in relation to proportion and vibration.

A GREAT MEDICAL AND DENTAL CENTER

A gift of $9,000,000 has been provided to establish in Rochester, N. Y., a school of medicine, surgery, and dentistry. The Rochester Dental Dispensary will furnish the clinic for the study of dentistry. The details of the project have been developed by Dr. Rush Rhees, president of the University; Dr. Abraham Flexner, secretary of the General Education Board; and George Eastman. The most modern laboratories for anatomy, physiology, and pathology, and a 250-bed teaching hospital are to be constructed, the hospital to afford clinical facilities for teaching purposes.

RATING SCALES IN INDUSTRY

A committee charged with the duty of reporting upon the value of psychology for labor misfits has declared to the National Association of Corporation Schools that it does not work out as a panacea for all ills. Such tests, they say, are merely to supplement and not supplant the usual employment procedure.

The Committee makes a distinction between the trained psychologists and a "great many pseudo-psychologists, vocational specialists, propagandists, and popular publications advocating the wholesale use of psychologic tests," as having been subjected to abuse and having failed to substantiate the fascinating possibilities claimed for it.

Puffed by Millions of Explosions

Puffed Wheat is whole wheat puffed to bubbles, eight times normal size.

Each food cell in wheat contains a trifle of moisture. We turn it to steam. Then we create in every kernel a hundred million steam explosions.

Every food cell is blasted. Digestion is made easy and complete.

The same process — Prof. Anderson's process—is used in Puffed Rice. And Corn Puffs are pellets of hominy puffed.

These three Puffed Grains are the best-cooked cereals in existence. And to millions the most delightful.

DEVELOPMENT UNDER PHYSICAL TRAINING

Service in the Army during the world war gave an average increase per man of 3.35 pounds in weight and 0.23 inches in height, according to compilation of the physical measurements of 873,159 men. The average weight of men on being inducted was 141.54 pounds and the average height 67.49 inches, which were increased at the time of discharge to 144.89 pounds and 67.72 inches.

A decrease of one-tenth of an inch in height was lost by American men between the Civil War and the world war. The average height at the time of the former was 67.6 inches.

HEALTH ORGANIZATION OFFERS COLLEGE FELLOWSHIP

The Health Organization of America offers one year in Teachers' College, Columbia University,—September 1920, to June, 1921,—for the study of modern health education in the elementary schools, to be awarded to the best graded plan and outline for interesting children in the establishment of health habits. Details will be furnished on application to the Child Health Organization of America, 156 Fifth Avenue, New York City.

PUBLIC HEALTH INFORMATION

The New York County Chapter of the American Red Cross has opened a bureau of public health information on the tenth floor at 119 West Fortieth Street. It plans to serve as a clearing house of information for the eighty-three public health agencies in New York County. General information will be given on all phases of public health activities.

CHLORIN TESTS IN INFLUENZA

Tests in a series of 184 cases conducted at the University of Arkansas under the direction of Dr. Harrison Hale were reported at the recent meeting of the American Chemical Society in St. Louis as tending strongly to bear out the theory that chlorin gas is effectual as an influenza preventive. Eight hundred treatments were administered to 184 volunteers who remained for five minutes daily in a room containing a small amount of the gas. In only one of the series did influenza develop, but it was agreed that the tests were not carried out to such an extent as to furnish conclusive proof.

DENTISTS ENDORSE HEALTH CENTERS

At its annual meeting in Albany the New York State Dental Society went on record as approving the provisions of the Health Center Bill which was introduced into the last Legislature as a measure to provide health care for the rural population of New York, and a committee was appointed to cooperate with other organizations interested in health for the purpose of securing favorable action upon the Health Center Bill at the next session of the Legislature.

DIAGNOSTIC WORK IN TUBERCULOSIS

A course in the early diagnosis of pulmonary tuberculosis and methods of treatment is offered by the Wachusett Medical Improvement Society at the Rutland State Sanatorium. Lectures will begin Thursday, May 20, and

Mixing Gelatine Desserts

ARISTON GELATINE DESSERTS

Have won their way to unquestioned recognition as the best which can be had.

The value of gelatine as a food is well known—its dietetic importance as a protein sparer, in combination with its acceptability as a dessert.

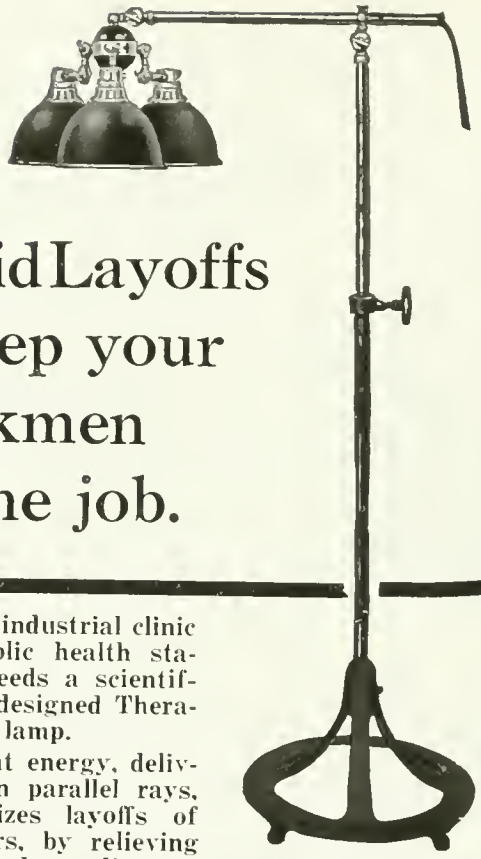
In preparation of Ariston Gelatine Desserts we use nothing but gelatine, cane sugar, fruit juices and citric acid—each of highest grade and purity.

Eight flavors: Vanilla, Strawberry, Raspberry, Orange, Lemon, Cherry, Grape, and Coffee; also plain, without flavor. In 6-pound cartons, one or assorted flavors.

CALUMET TEA & COFFEE COMPANY

409-411 W. HURON ST. CHICAGO

"Dealers Direct With You"



Avoid Layoffs —keep your workmen on the job.

Every industrial clinic or public health station needs a scientifically designed Therapeutic lamp.

Radiant energy, delivered in parallel rays, minimizes layoffs of workers, by relieving pain and speeding recovery through the use of

Thermolite
LIGHT AND HEAT INFUSER

Delivers Radiant Light and Heat in PARALLEL Rays
for the treatment of

Neuralgia	Rheumatism	Chronic Ulcers
Sprains	Neuritis	Local Infections
Lumbago	Arthritis	Dysmenorrhea

and many other conditions.

Because the rays are parallel, they bring quick relief from pain, reduce inflammation, and promote healing.

ThermoLite is supplied in two forms—the Triplex for hospital clinics and office use, and Simplex (single lamp with or without stand) for home use.

H. G. McFaddin & Co.

39 Warren St., New York City

(Continued from page 30 Adv.)

will continue Thursday of each week until June 24. The object is to promote the early diagnosis and control of pulmonary cases. The course is open to all physicians. The facilities at Rutland for the demonstration of all phases of the work, the range of subjects, and the personnel of the lecturers give ample assurance of the value of the course.

RATING OF BODILY MECHANICS

A physical examination of the first year Harvard men by Roger I. Lee, professor of hygiene, disclosed bad postures in 80 per cent and only 0.97 per cent were rated as having a good mechanical use of the body; 34.8 per cent used their bodies very badly.

"To be sure," says Dr. Lee, "their poor bodily mechanics is offset by youth and a physical condition otherwise good, but the result of this test certainly suggests that our preparatory schools might do much toward preventing poor habits of bodily use, and also that it is desirable for the college to undertake correction."

The good results of enlightment noted in the almost uniformly good condition of the teeth and the universal correction of ocular defects promise correction through physical education to bring to their best development the postural defects in these young men otherwise organically sound.

MEDICAL STUDENTS IN PRUSSIA

The *Deutsche medizinische Wochenschrift* announces in the issue of May, 1920, that medical students at the university now number 2,280 in medicine, 200 in dentistry, and 130 in pharmacy, this in a student community of 7,724 members, the number of these special students having doubled in the last five years. Five years ago the proportion of physicians was one to fifteen hundred people. The population having decreased, it is expected that within a very short time the proportion will be one to one thousand. The Prussian Minister of Public Instruction has stated that professorships in the universities are now open to both sexes.

HEALTH MEETING AT VANCOUVER

A joint congress was held at Vancouver, B. C., the week of June 21, 1920, between the Canadian Public Health Association, the Canadian Medical Association, the Canadian Association for the Prevention of Tuberculosis, the National Committee for Mental Hygiene, and the National Committee for Combating Venereal Disease. The meeting was of special significance in that statement was made of the Canadian health program for 1920, and joint discussions brought out both the needs of the field and the available measures for meeting them. Charles Lyman Green, M.D., of St. Paul, Minn., delivered an address on medicine before the Medical Association.

DR. HEKTOEN ELECTED PRESIDENT

The Chicago Medical Society, at its annual business meeting, elected the following officers: President, Dr. Ludvig Hektoen; president-elect, Dr. John S. Nagel; secretary, Dr. Hugh MacKechnie; treasurer, Dr. Clarence Leigh, counselors, Drs. J. H. Walsh, R. R. Ferguson, Joseph L. Miller, Malcolm L. Harris, John M. Jacobs, Jr.; alternate counselors, Drs. John F. Van Paing, Edward J. Devine, Daniel Lynch, Harvi Mai, George Griffin.

The roster of the organization, it was announced, was increased by 300 names in the last year. There are now 3,586 members.

CHRONIC DIARRHOEA

Ada Tungate—a case of Tubercular Peritonitis. Emaciated, abdomen distended, temperature 101. Physician prescribed spoonful of VIROL with whey every two hours. In one month the diarrhoea had ceased, child was normal, with weight increased. Doctor continued feeding VIROL for some months longer, substituting milk for whey. Child completely restored to health.

Diet In Infantile Diarrhoea

To each half pint of barley water or rice water add a half teaspoonful of VIROL and give one or two ounces of the mixture every two hours.

The role played by Virol in the treatment of diarrhoea has been elucidated by the remarkable recent researches upon phagocytosis.

There can be no reasonable doubt but that the marvelous results produced by virolizing the diet of both breast- and bottle-fed children are due to the opsoninogenic properties of the preparation.

It has been conclusively proved that the addition of Virol under suitable conditions enormously stimulates the phagocytic powers of the white blood cells.

Virol is composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars:
50c, $1.00 and $2.00.

Liberal samples of VIROL and interesting literature will be mailed to physicians on request.

COLONIES FOR FEEBLE-MINDED

Dr. Charles Bernstein, superintendent of the State Custodial Asylum, Rome, N. Y., reports the experiment in agricultural colonization of high grade mental defectives carried on in New York since 1906. At present there are ten farm colonies for boys, all self-supporting after the first year. These farms cost the state from five dollars to ten thousand dollars each. The purpose of these colonies, as stated by Dr. Bernstein, is "to test out the boys and girls in an institution more nearly normal than is possible in a large institution. They live at first in the colony house, going out to work by the day. Later, if proved trustworthy, they are allowed to live at the house where they work, using the colony house as a social center for their leisure hours."

BELGIUM ESTABLISHES CHILDREN'S BUREAU

A children's bureau "to encourage and develop the protection of childhood" has been established in Belgium along the lines of the Children's Bureau in the United States. Direction will be by a central board of forty members with committees of six to twelve members in each province. Supervision of the local agencies will be under local committees and local authorities. Among other things, the infant consultation centers will provide regular and free examination of all children under the age of three in families under the care of the centers; free medical consultation service for expectant mothers; organization of educational work along lines of hygiene, and supervision over placed-out children under seven years of age.

OHIO SOCIETY CHANGES NAME

At the annual meeting of the Ohio Society for the Prevention of Tuberculosis, held in the city of Columbus, May 13, 1920, the name of the Society was changed to Ohio Public Health Association. This change was effected because of the fact that the Society had been doing other than tuberculosis work in the past and to place the organization in a position to keep abreast with the rapid strides being made by the State Department of Health. The new constitution of the Association provides as its object—"the prevention of disease, with particular reference to the prevention of tuberculosis."

A FEW GENERAL HEALTH RULES

A rational course of cooperation in matters of health and conservation was outlined by the National Women's Christian Temperance Union in a health pamphlet containing the following paragraph:

Don't dress so thinly that it will take more coal to keep you warm. Don't stagger about on high heels, for we must work like men. Cooperate with government plans for food conservation. Be ready with good wheatless and meatless recipes. Do all within your power to save 100,000 additional babies this year. During these very strenuous times we must strive to be at our best physically, mentally, and morally. We must do all we can to teach the people the laws upon which health depends.

THE WORK OF INDUSTRIAL NURSES

At the third annual dinner of the Industrial Nurses' Club of Chicago, held recently, statement was made that more than 100,000 first aid treatments for coughs, colds, bruises, and serious injuries were administered last year in Chicago industrial establishments. The speakers on the program were Dr. Harry E. Mock and Dr. Orlando E. Scott.

SANITARY LAPSES

NOT long ago a campaign against the common drinking cup swept the country and in an incredibly short time laws and ordinances were passed in nearly all states and cities prohibiting the use of the common cup. No sanitary campaign has ever had such immediate and complete success as this one.

The common drinking cup was displaced largely by the drinking fountain. Various designs of such fountains were installed, usually without much study of the important question whether they would prevent the spread of infection. After installation they were frequently subject to neglect. The results may be seen in almost any tour of observation. Through faulty design, improper installation, lack of repairs, or lack of free flow of water, many fountains are a greater menace to health than the death distributing common cup.

The subject is one for sanitarians and health officers to deal with vigorously. Every day millions of people in industries, schools and public places drink from these fountains. Neglect in permitting improperly designed fountains to be installed, or defective ones to be continued, is a serious lapse from the high zeal which eliminated the common cup.

MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

THE annual conference of the American Public Health Association is to be held in San Francisco, September 13 to 17. The program will cover such important topics as health centers, organization of child hygiene, mental hygiene, narcotic control, food poisoning, and special matters relating to Western health problems. The divisions of the Association consist of Public Health Administration, Laboratories, Vital Statistics, Sociological, Sanitary Engineering, Industrial Hygiene, Personal Hygiene, Child Hygiene, and Food and Drugs, besides the general sessions of the conference.

THE NORM OF HUMAN NUTRITION

THERE are many cases of patients trying to recover from diseases on a diet that would not make a rat grow, nor keep it alive longer than one-quarter its normal term of expectation of life, says Elmer V. McCollum, in an article which appears in the July issue of the *Public Health Nurse.* Shortage of calcuim is one of the fundamental problems in human nutrition, and a dearth of vitamines the other. A great many people, particularly the employed groups, are living to the extent of 90 per cent or more of their food supply on foods badly chosen from the standpoint of their welfare. The appetite cannot be regarded as a safe guide at all for the nutrition of man or animal.

Biological methods in the laboratory have demonstrated the special dietary properties of foodstuffs so that it is possible to make diets which will produce normal or approximately normal growth, and to charge to certain faults in the diet —that is, faults of a secondary character—a rapid or premature development of senility. "We have a few people who are retaining the full vigor of adult life to an advanced old age," says Dr. McCollum, "but how many people do we see who are at thirty-eight or forty looking as old as they should fifteen years later," the point emphasized being that we are accustomed to regard as normal

something which is far below it in human nutrition, and the greatest single factor in the improvement of public health in this country is the improvement of the nutrition of the children.

A demonstration in nutrition among the children of an orphans' home resulted in gains in the weight of under-nourished children of from 50 to 70 per cent of their body weight in eight months time. The fundamental basis of all health is nutrition, and the biggest thing that can be done for improving the health of the people is to feed them right. There is no sense, says McCollum, in studying industrial fatigue, for instance, until it is first known that the individuals are well fed.

New classifications of foodstuffs are called for, based on the function of the article as food instead of on its chemical composition. In connection with the nutritional work among children he emphasizes (1) educational work among the children themselves and among the parents; (2) the keeping of records on the weight and measurements of all children, noting whether they are keeping the normal rate of gain. Milk is to be added to the diet, the unique dietary properties of the leafy vegetables are to be urged, and meat portions are to be cut down to about half the quantity to which we are accustomed.

S. P. M.

ROYAL MEEKER GOES TO THE WORLD LEAGUE

Dr. Royal Meeker, newly appointed director of the Scientific Division of the International Labor Office.

DR. Royal Meeker, who for seven years has been the United States Commissioner of Labor Statistics, has resigned to accept the position of Director of the Scientific Division of the International Labor Office, under the League of Nations. Dr. Meeker sailed for Geneva July 31 to assume his new duties. He will be principally engaged in the organization of the scientific office and in editing the *International Labor Bulletin* and other labor publications of the League.

The work of Dr. Meeker as Commissioner of Labor Statistics has been of special interest to physicians and social workers. Being keenly aware of the rôle of health and medicine in social and industrial problems, he gave a large amount of his time and that of the Bureau to the investigation and publication of data relating to industrial hygiene, medical care under compensation acts, budgets and the cost of living, health insurance, and rehabilitation of cripples. As secretary of the International Association of Accident Boards and Commissions, he did effective work in establishing higher standards among the industrial commissions and in emphasizing medical and social aspects of compensation laws. He has been a regular attendant at the conferences on public health, industrial hygiene, and social work, and has participated with rare power in the discussions.

The selection of Dr. Meeker to his new office is a recognition of his personal ability. Since the United States is not yet a member of the League of Nations, it was a special honor to be chosen to the important place which Dr. Meeker is to fill. His new position is one of great possibilities. The Scientific Division of the International Labor Office will be the center for the collection of data on labor conditions from every nation in the world. It will be ultimately the greatest source of scientific data available for the use of the governments of the world in solving labor problems, particularly the problems of health and well being of workers.

MODERN MEDICINE congratulates Dr. Meeker upon his new honors, but more particularly upon his new opportunities. In due time the world will come to seek his counsel on industrial betterment in the same way that the forward looking men and women of the United States sought his counsel during the last seven years.

THE CRITERIA OF SOCIAL PROGRESS

ONE hears on every side indictment of the present period as being one of class conflict, and claims are urged that the existing disorganization and class conflict exactly parallel conditions which preceded the fall of Rome. The postulate is as strenuously asserted that a new and better era is assured by the interest, never so general as now, in child nurture and other welfare movements looking toward physical and social betterment, and in the enlargement of the sphere of woman, who represents, not merely a sex, but a suppressed and dominated class.

Destructive criticism is as futile on the one hand as unwarranted complacency on the other. An exact estimate of the situation is called for, and a cool judgment on the basis of facts. Nor does it suffice to pay attention to but one aspect of the subject. Real progress must be well balanced and must proceed from different angles. The welfare of a people is not to be judged merely by material possessions. There is a direct relation between extreme poverty and the incidence of disease, but a satisfactory financial status does not insure right living, nor its lack necessarily spell disaster. The fact is not to be lost sight of that conditions of extreme wealth may be as inimical as poverty to real welfare. Over-emphasis of any single phase of the question is to be guarded against in framing a well thought out program that will reach all classes and take cognizance of all conditions.

We have been interested recently in the work of Todd[1] in formulating the conditions of social advance. He considers that interest in human well being is the basic test of general advancement. This interest must become more and more conscious and rationalized, must be purposive, and must have a projective aspect for the direction of future programs. Progress is not written in the nature of things, but comes as the fruition of conscious and persistent effort.

He formulates five basic tests for the validity of claims in regard to progress, the first two of which are of interest to physicians and health workers in particular. The population test would involve a high average expectation of life, no perceptible deaths from need or misery, increasing fitness of the average individual, steady improvement in the arts of life, and rising standards of living. Under his second test of increasing health and longevity he quotes an American representative of the medical profession as declaring that "the average length of life is the one and only sure index of whether the world is growing better; it is the unemotional but inexorable measuring rod of real social progress that can be told in figures. Other standards of measurement there are, but they are mostly vague, and founded largely on faith and hope. Here are statements that are based on definite statistical facts.

"In spite of many protests to the contrary, both health and longevity seem at the present moment actually to be on the increase. Throughout practically the whole of the western world the death rate is pretty steadily declining. M. Levasseur by comparing statistical studies of France in the eighteenth and nineteenth centuries discovered an increasing vitality in the French population, measured by decreasing or postponed mortality. Prof. P. C. Mitchell states that the mean duration of life in France rose during the nineteenth century from twenty-nine to forty years. In the United States the average age at death was 31.1 years in 1890, 35.2 in 1900, 38.7 in 1910. The average age at death is of course not to be confused with the average expectation of life, but it may be taken as an approximate measure of it; and in the absence of accurate life tables in the United States we have to content ourselves with such rough approximations. In Germany, within the last twenty-five years or so, average longevity has risen for males from 38.1 to 48.85 years; for females from 42.5 to 54.9 years. Professor Finkelnburg estimates that the average length of human life in the sixteenth century was only between eighteen and twenty years, and that at the close of the eighteenth century it was a little over twenty years, while today it is between thirty-eight and forty years,—a gain of 100 per cent in three centuries. Prof. Irving Fisher comes to the same conclusion from life-span records of Geneva, running back three centuries: they indicate a rise in the expectancy of life from 21.2 years in the sixteenth century to 39.7 in the nineteenth. As to the criterion of decreased physical suffering Doctor Osler writes. '. . . Measure as we may the progress of the world . . . there is no one measure which can compare with the decrease of physical suffering in man, woman, and child when stricken by disease or accident.' And Dr. E. T. Devine, who quotes the words with manifest approval, concludes that on the whole humanity meets this test and that health is rising.

"But we must remember that a pasteurized, sanitized society is not necessarily progressive nor dynamic. Health, long life, sanitation are contributors to social well being, but are not its only benefactors; they make it possible, but do not guarantee its increase or permanence." S. P. M.

THE CHILD HEALTH ORGANIZATION

By L. EMMETT HOLT, M.D., Chairman, Executive Committee, New York City

THE Child Health Organization was formed in the spring of 1918 for the purpose of improving the health of children of the school age. Surveys in schools in different parts of the United States had shown both in city and country fully 20 per cent of the children attending school to be suffering from malnutrition, that is, they were so much under weight that their condition should be regarded as serious. Besides, the selective draft had shown how large a proportion of the young men were rejected for physical defects or undernourishment. The consequences of the condition in school children were much preventable illness, much poor work in school due to purely physical causes, and a generation of boys and girls growing up who were physically definitely below par.

The program of the Child Health Organization has included four definite items: (1) To make the teaching of health an essential part of education in all schools; (2) to encourage and promote nutrition classes for the undernourished, and to improve health and nutrition by school lunches; (3) to educate nurses, parents, teachers, and others as to proper foods for growing children; and (4) to extend and improve medical school inspection and the removal of defects interfering with their growth.

The first step in any well rounded health program is to weigh the children once a month and have them record their weights on the class room weight record

Since the methods used to accomplish the last three mentioned parts of this program have not differed essentially from those previously employed, we shall discuss in this paper chiefly the ways and means by which the first one, *viz.*, teaching health to children, especially in the schools, has been attempted and the degree of success which has attended effort in this direction.

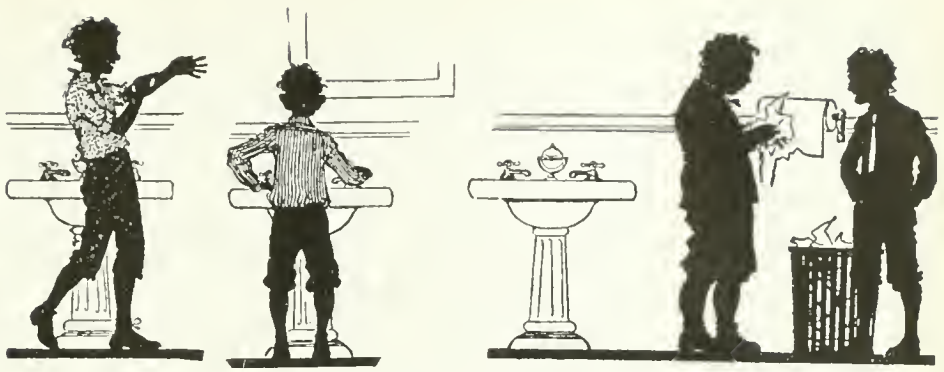
In this work we have had the active cooperation and support of the Federal Bureau of Education through Commissioner Claxton, and Secretary Lane of the Department of the Interior, and, later, of his successor, Secretary Payne. This has been made possible by the appointment of one of the staff of the Child Health Organization to a position in the Department of Health Education of the Bureau of Education.

It is recognized that all health measures which lead to permanent results must rest upon an educational basis. By the education of the mother in infant feeding and hygiene the very marked reduction in infant mortality has been brought about in the last fifteen or twenty years. This reduction in New York City has brought the infant death rate in a generation to one-third the former figure.

A knowledge of health laws is not instinctive; if children are to know they must be taught. It was believed that the health problem of the school child could not be solved without teaching the child himself and securing his cooperation. It was equally clear that before a child can be taught or influenced in any way he must be interested. How to make health interesting, therefore, was the first aspect of the problem which the Child Health Organization has found it necessary to solve.

Teaching health to adults is always difficult and usually unsatisfactory, and the greatest mistake made in health education in the past has been that the instruction has been directed almost entirely

to the adults of the community. It is hard for them to unlearn what they have been taught in childhood. They are often grossly ignorant in regard to the nature of disease, how it is caused, how it is spread, how it can be prevented. Their superstitions and prejudices make it difficult to influence them. Their minds are very resistant to new ideas which affect such fundamental things as their food and their health habits. It is found most difficult to make them follow the simplest rules, even for the protection of their personal health in the so-called dangerous trades in which special precautions are necessary to prevent disease.



The routine of the school day should be so organized that it will afford an opportunity for continuous practice in the ways of health.

It is becoming increasingly evident that we have begun too late with our health instruction. The child is the fittest subject in which to instill proper health knowledge. He has no prejudices to overcome. It was believed that if right methods were employed it would not be difficult to interest the child in health or to influence him in the formation of good habits. In most matters habits are not yet formed and it is almost as easy to form good habits as to form bad ones. All of these things combine to make childhood the golden period of life in which to teach health.

While the education of the mother in the care of the healthy infant has reduced infant mortality, for several reasons this has as yet accomplished very little so far as the health of the older children is concerned. The first and perhaps the most important reason is because of a lack of knowledge by the mother herself in regard to the health rules which should be taught and the health habits which should be practised by older children; and, secondly, a lack of interest on the part of the mother in this problem. She can more easily grasp the importance of obeying the health rules taught her regarding her baby, for unless properly fed and cared for, she can see that the baby does not thrive and that he may die for lack of precaution in these matters; whereas, she does not so readily appreciate that failure in regard to the older children have results which are less obvious but which may be shown in such conditions as general malnutrition, slowness in growth, anemia, chronic indigestion, extreme nervousness, want of concentration, or poor work in school, etc., —things which have a highly important bearing upon the ultimate physical development and vigor of the child. It must be admitted that we as physicians have not always given the mother the direction and help she needed.

Health Should be Taught in the Schools

Again, the home control by the average mother of the child after he has reached the school age is usually lax and in very many cases is entirely lost. When a child has reached this period in his life, some influences other than those of the home must be brought to bear if a strong impression is made upon his life, certainly in matters of health. We are forced to the conclusion that the school is the place where health instruction must be given to most children, if they are to get any proper health instruction. Although it may perhaps seem to many that the curriculum is already over-crowded and that school teachers are overworked, it would seem that a place must and can be found for such instruction of the right sort in the schools. The school curriculum needs some radical vision, and a departure from the old deep-worn ruts is surely worth consideration.

Certainly the opportunity which the school offers for health education has hardly been recognized. In the school the child is under continuous observation for eight or nine years; his attendance is compulsory; he can not if he will altogether escape the influences of education; and the school has the machinery for teaching. The opportunity here to give instruction to children in groups is very important, for it is usually found that instruction to groups can be made more impressive and commands more attention than that given to an individual child. Again, the long period of school life permits a great variety of health teaching, from the simplest things taught the youngest, with graded instruction for those who are older, to the wider knowledge which can be given the oldest. Much more can be done in school than even in the most enlightened homes; in fact, the home itself is often best reached through the child.

Now exactly what do we include under health teaching? How much health knowledge can be imparted to children by teachers who are not health experts and who have not had the advantages of special training?

The Health Instruction Given to Children

There are clearly two distinct kinds of health instruction. One of these relates to matters of public or social health and is largely concerned with the prevention of diseases which may spread through the community. The relation of these scourges to faulty hygiene and sanitation, the fact that they may be spread by unhealthy persons who handle food, or through contaminated milk or water supply, or by mosquitoes, flies, rats, lice, or other vermin, and that many of these diseases can be communicated from one person to another —all are things which may easily be understood by older children. They then come to recognize the importance of sanitary laws for a community and will generally be found to be the most conscientious observers of these laws. They can appreciate what it means to have the milk and water supply of their city closely watched by experts, the value of clean streets, the necessity for proper disposal of sewage, and garbage. They can understand also why quarantine is necessary in communicable diseases and readily accept this curtailment of individual liberty for the sake of the rest of the community.

The results of the campaigns against tuberculosis, malaria, typhoid, yellow fever or small-pox should be made familiar to all, and there is no reason why much of this should not be given in the schools. These stories, when properly presented by one who knows how to write for children, can be made interesting, even thrilling.

The economic value of health is something even a child can be made to appreciate when he is shown, for instance, what it has meant to the prosperity of some parts of the world to get rid of malaria and how this made possible the building of the Panama Canal.

Much good health literature for children has appeared in the last few years, but very little of it has as yet found its proper place in the schools. If only we can get the children in our schools *interested* in the great public health problems, it is not going to be difficult to secure adequate health legislation or public support for the enforcement of any advanced health measures which may be in the future become necessary. The older children in our schools will very soon form our voting population and their education along the lines suggested is most important if we are to have a public intelligent in these health matters.

The other phase of health instruction is that which might in contrast with the foregoing be termed private or personal, and this seems much more important even than the foregoing inasmuch as it is concerned with the *promotion of health* rather than the prevention of disease. It is to be carried on along quite different lines from those employed in instruction in public health. It should be begun with little children of six or seven years. Here the chief purpose should be to stimulate the formation of good health habits; the aim, to rouse to action, not simply to teach rules. For this end only such knowledge of the functions and needs of the body is required as to make the child understand what is necessary for its protection and care, or enough to form the basis of good health habits.

The child can easily learn the essential needs of his body, such as proper food, cleanliness, fresh air, exercise, rest, regular bowel movements, etc.; also the things that do harm, as improper food, decayed teeth, excess in eating or drinking, lack of proper sleep, the use of tea or coffee, alcohol, or drugs. It is self-evident that before children can be influenced they must be interested. How to do this is the problem. The aim of the Child Health Organization is to get instruction in all these matters into the school as a part of daily routine.

Methods of Arousing Interest

The interest of many children, especially those under ten years of age, can be created by the credits given for regular performance of the so-called "Health Chores" of the Modern Health Crusade and various health leagues. When these "Chores" have been repeated a sufficient number of times, the hope is that they may become fixed habits. The practical objection to many of these organizations is their complexity and the amount of time required not only by pupils but by teachers in carrying out the scheme. It is argued that the novelty of these things wears off after a few weeks or months, and something more than the reward of the gold star is needed to secure the effort necessary for permanent results.

CHO-CHO, the health clown (christened with the initials of the Child Health Organization), is a professional clown who entertains large groups of children while he instructs them in matters of food and hygiene. The following communication from a teacher indicates the reaction to his appearance in a public school in Chicago:

We plan to send you compositions from every grade, concerning the marvelous lesson that CHO-CHO gave to more than 1,700 children and forty-four teachers on "What is Good for Children." He is a real teacher and a marvelous one. He held the children enthralled for over

an hour and he taught them many, many valuable things in such a brief period—so much indeed that we wonder if we do not lose time sometimes as teachers by being so humdrum and undramatic. CHO-CHO stirred us all up, literally and figuratively; please send him to us again some time. The children's opinions will follow later. With deep appreciation for this rare pleasure.

The "Picture Man" is a cartoonist who entertains large groups by amusing sketches relating to foods and health habits while he discourses on these subjects.

The "Health Fairy" is a trained nurse of magnetic personality who interests the children by fairy stories which teach health lessons. The above are all agencies designed by the Child Health Organization to introduce the subject of health to young children and serve to awaken primary interest; they are followed up by other methods. Valuable use has been made of the dramatic instincts of children in the production of little health plays, and they have even been encouraged to write such plays themselves. In brief, the effort is made to make health instruction play in some form, with the belief that in this way greater interest can be roused and a deeper impression made. Children are taught to make health posters of their own, as these have for them far greater value than posters done by the best artists. This work must be stimulated and guided by those who know child psychology.

In such ways the essential facts regarding necessary foods and food values and important health rules can be impressed upon the child, who is quite unconscious of the fact that he is being taught physiology and hygiene.

Attractive literature has been produced with pictures and health rhymes for little children which has had a wide influence. The most important piece perhaps is the Child Health Alphabet by Mrs. Frederick Peterson, of which already more than 2,500,000 copies have been distributed.

Group Competition Employed

Probably the simplest and most widely useful of all the means of interesting children of all ages and one which involves the least time and labor in its application, and the most potent influence in maintaining an interest in the observance of the rules of health, is group competition based upon the record of height and weight. Largely by means of the scales, the mother has been taught the meaning of the weight of infants and the importance of an increase in weight as a measure of her baby's progress in health.

It is the state of nutrition which the scales record, and normal nutrition in infancy spells health. In older children, also, the same thing holds true to almost the same degree. Here also the condition of nutrition is a good index of general health—the best index, we believe. This is shown first by the child's weight for his height, and afterward by his regular progress in weight. Normal growth and development depend upon the nutrition of the body; the things which affect nutrition are therefore the most important ones which must be emphasized in health education. To the physician the essential habits of daily life which are necessary to healthy growth are known as the laws of health; to children they are taught as the "rules of the game" and are practised by them in the spirit of a game—a competitive game, too.

Weight contests have been widely used. Those who are up to normal weight for height receive a yellow tag, and those who are below, a blue tag. The normal weight for the child's height is placed on one side of the tag and also his actual weight. On the reverse are simple health rules which all children should observe.

Where weights are taken in school they are entered each month upon a special class room weight record which has been distributed through the Bureau of Education by the hundred thousand to schools all over the country. The influence of this is very great, as the weight is something concrete which the child's mind can grasp. Such weight records and the health teaching which can be tied up with them are continued throughout school life.

Let us see how this works out in practice. There must of course be scales in all schools, so that every child is weighed and measured at the beginning of the school year and weighed monthly thereafter. The weighing time is a solemn occasion—a sort of monthly day of judgment. Each child is anxious to maintain his standing and to make progress. When the results of the weighing are known, one teacher comments to the class somewhat as follows:

Now will all the children who are up to their normal

It is the purpose of the physical examination to discover a child's strong points as well as his latent weaknesses and incipient physical defects, so that his health regimen may be closely adjusted to his individual needs.

weight for height stand up. Children, I could tell it by your looks—your bright eyes, your rosy cheeks. I could tell it by the way you play at recess, by the way you stand, by the way you carry yourselves when you walk, by the kind of work that you did in school last month, etc.

Now I want all who gained in weight last month to rise. That is fine!

Now boys won't you tell us how you did it?

Many hands go up, each anxious to tell his experience. No comment is made upon those who are below weight, nor on those who have lost weight in the month. It may not be the child's fault. There is constant praise and encouragement for those who succeed, but no word of condemnation or reproof for those who fail. It is not needed. In such a school health becomes "the thing," and a public opinion has been created which nothing can withstand. The child is competing not so much with his mates as with his own record. One child came to his teacher and said confidentially: "Something dreadful has happened."

"Why, what is it, Henry?"

"Do you know that I lost a pound and a half last month?"

"I'm so sorry," said the teacher.

"But," Henry continued, "I think I know just what did it. I was going to bed at half past nine when I know I ought to be in bed at eight. I'm not going to be caught that way again."

This is the way we brush our teeth, brush our teeth, brush our teeth—all on a Monday morning!

Essentials of Health are Simple

When a child is found much below weight, when he is not gaining or when he is losing weight, he is at once anxious to know why. Which rule is he breaking, the one relating to food, to hours of sleep, tea and coffee, or what? Now is the occasion to stress the health rules. He is eager to learn; he wants to be in the healthy group. He is ready to submit to a medical examination, willing even to have tonsils and adenoids removed or teeth extracted, if these seem to be the cause. As these records of health progress go home to the mother on the monthly report card, her interest is soon awakened and with little difficulty her cooperation can be secured; in fact, the child's zeal often makes this inevitable.

When a child has learned in school that to get up to his normal weight or to gain weight he must go to bed at eight o'clock and not play in the street till ten or eleven; that he must drink milk, not tea and coffee; eat regular meals and not fill his stomach with trash between meals; must eat a variety of food cereals, green vegetables, fruit, etc.,—does anyone for one moment believe that such habits formed in childhood during school life will not make a lasting impression upon the life of the individual? Too much emphasis cannot be placed upon the fact that the essentials of personal health are such simple things as these, and that even the untrained teacher, once she is interested, can carry them into effect.

Just now one of the greatest needs is the development of systematic graded courses for health teaching for children of all ages, from the primary grades up to the normal schools. This is the problem which at present is engrossing the attention of the Child Health Organization. With the youngest we must begin with the simple, the dramatic and picturesque, the things which touch the child's imagination. Other more serious things taught in other ways must follow. In all this instruction the emphasis must be placed upon the *promotion of health*, not upon the avoidance of disease. We must appeal to the play spirit and learn to utilize it in our health teaching.

Let us not deceive ourselves with thinking that already there is sufficient health teaching in the schools through instruction which is given in physiology and hygiene and in domestic science, or even in much of the physical education as now carried on. This instruction has not brought about the results which we are seeking. The reason for failure is that it has not been linked up with practical life. It has influenced the every day health habits of the child little more than his study of arithmetic or botany. Other methods than those previously employed must be used if the end we seek is to be attained.

When a group of children in a school has been weighed and measured it is found that a certain number are much below weight for height, are not making normal progress in weight, or perhaps are making no progress at all. These are brought together in a special group for particular, individual study to discover the cause and, if

possible, remove it. First of all, a general medical examination should be made to ascertain whether the condition depends upon some disease such as cardiac disease or early tuberculosis, whether it is due to some defect which interferes with normal growth, such as large tonsils, adenoids, or carious teeth, or whether it is due to bad habits, such as late hours and lack of sleep, or to insufficient or improper food.

The children forming the nutrition class need to be weighed weekly and seen frequently; cooperation with parents must be secured, and the children kept under close observation until the faulty conditions have been corrected and their general health improved. The nutrition class is probably the most important newer health agency of this decade and bids fair to accomplish for older children what the milk station or "consultation" has done for infants. But such classes are needed, not simply for the under-nourished, to bring them up to normal, but for those whose condition is now good, that they may be kept well and reach the best physical development of which each child is capable.

The School Lunch

The importance and value of the hot school lunch in improving the nutrition of children has long been recognized in Europe, and in this country it has been widely pushed in recent years. The Child Health Organization has especially stressed the educational value of the school lunch, pointing out the great opportunity which is here offered to teach children foods which are proper and necessary for growth, food values, and food costs. Especially has the value been urged of teaching children of foreign parents to eat our American foods. This is not difficult when children are fed in groups, but almost impossible when they are taught singly.

Medical School Inspection

The chief points in medical school inspection which the Child Health Organization has endeavored to secure are that every child on entering school should have a complete physical examination and that this should be repeated once every school year. Such examination should be made not for the exclusion of contagious diseases, nor the recognition of defects such as those of vision or hearing, carious teeth, enlarged tonsils, and adenoids, but to determine the condition of the child's nutrition and seek other causes than those mentioned which might explain his impairment.

Efforts have been made to secure from school authorities and teachers a recognition of health as an essential subject of education, to consider the importance of health conditions in relation to the intellectual work of the children, and, more than all else, to secure cooperation between the schools, the health authorities, and the home in making effective the program outlined at the beginning of this article.

Although the Child Health Organization has been in active operation only a little more than two years the methods which it has developed have now been duplicated and many features of its work have been extended to every state in the Union and to many foreign countries. One of the points which was first stressed was the necessity for placing scales in every school. Four thousand replies to a questionnaire sent out broadcast over the country through the Federal Bureau of Education show that scales have already been placed in one-fifth of the schools of the country.

STEWART SUCCEEDS MEEKER

Ethelbert Stewart, United States Department of Labor Statistics.

Ethelbert Stewart, long identified with the United States Bureau of Labor Statistics and the Department of Labor in various capacities, has been appointed Commissioner of Labor Statistics to succeed Dr. Royal Meeker, who resigned to assume the position of Director of the Scientific Division of the League of Nations, Labor Division.

The appointment of Mr. Stewart assures the friends of the Bureau that the policies which have made it one of the foremost social agencies of the country will be continued.

THE PSYCHOLOGY OF THE SICK CHILD

By A. LEVINSON, Chicago

THE sick child differs from the well child not only physically, but also psychologically. Not all children react to disease in the same manner, nor do all diseases produce the same mental reaction in a given child, but, as a whole, there are certain psychological changes which take place in the sick child that are characteristic of practically all sick children and of nearly all the diseases to which they are subject.

The child explores its environment through progressive activities, instinctive at first but gradually coming under its own volition and becoming coordinated as its various gestures gain meanings and become associated with accomplished ends.

When its interest is awakened, deliberate imitation and conscious copying of the acts of the people develop the adaptations society requires of the individual.

A wholesome environment, with intelligent direction, during the plastic period of childhood enables the fullest possible development of individual and social capacities. This applies not only to the well, but even to the sick child.

In order to understand the sick child, naturally one must know the healthy child. It is therefore pertinent to discuss first a few essential points in the psychology of the healthy child.

The child's mental attitude is not fixed; it is constantly moving, continuously progressing. There is the newly born child, who apparently knows nothing more than to crave for food. Before long the same helpless baby begins to coo, to recognize persons about it, to talk, to walk, perfecting himself progressively. Certain mental peculiarities, however, are retained all through infancy and childhood, the following being the most constant:

Infants Are Normally Active

The normal child, from birth to adolescence, exhibits a more or less constant desire to do something. Normal infants are constantly active when awake. Sometimes they expend energy in playing, by swinging their arms and by kicking their feet, thus exercising the muscles of the extremities. Sometimes they expend energy by their vocal cords and laryngeal muscles by crying and talking; at other times they exercise the muscles of their jaws by eating or making grimaces. At times one wonders how it is possible for an infant, or for a child of three or four to be active from early morning until late at night. The child appears to have double, triple, and perhaps even tenfold the amount of energy of an adult. The amount of energy expended by a child two or three years of age is tremendous in comparison to the body weight and height. Play, which is usually considered as one of the fundamental characteristics of infancy and childhood, may be regarded as a subheading of work. Play, as indulged in by a child, is simply a form of work in which all the different muscles are more or less vigorously exercised.

If proof is wanted to the theory that man is the outgrowth of an ape, the quality of imitation may supply it. Almost everything the child learns to do is acquired through imitation. The connection of imitation with the problem of child education is well worth keeping in mind. The only function that the child does not acquire by imitation is that of eating, and, while the craving for food seems to be an inborn instinct in the baby, it is possible that closer observation may reveal that even some aspects of the act of taking food are acquired by imitation.

The Child's Imagination Wanders

Although a strong imaginative sense survives in comparatively few adults, we find that all children or, at least all normal children, possess a remarkable power of imagination. It is no mere incident that most children like fairy stories. There is something in a fairy story that fires the imagination of the child, that carries him away to other spheres, that gives his imagination a chance to stretch to worlds not limited by time or space. It is to be regretted that children cannot express their imagination in writing, and that few writers know the child mind well enough to picture the flight of childish imagination. Were the child able to give expression to his imagination on paper, we would no doubt have a poetical literature the like of which has never been seen. The child is able to picture incidents in life that to our cold-blooded minds appear impossible. We, who see everything from the standpoint of bread and butter; we, who measure space by yards and miles, and time by minutes and hours, cannot let our imagination wander very far. As soon as we conceive of incidents that seem to be a little

*Reprinted from the *International Clinics*, 1920, Vol. ii, Series 30, by courtesy of the J. B. Lippincott Company.

out of the way, our limited, but at the same time materialistic experience confronts us and stops us; our fancies are censored; this is pronounced impossible, and that unplausible. The child mind, however, admits no limitations of time or space. What is to us a day or an hour may seem to the child a thousand years. Imagination plays one of the greatest rôles in the life of the child. He hobnobs indiscriminately with prince and pauper. He taken delight in acting the part of his imaginary hero, who is sometimes a king, sometimes a mighty general, sometimes a wonderful magician. He revels in the art of everyday make-believe. He will pretend that he is his own father, mother, sister, or brother; that he is a dog or bear; a puffing steam engine; and what not. Nothing is too good or too bad for him; nothing too big or too small. His breadth of imagination transforms everything.

Fearlessly Demands Justice

For years, nay, for centuries, people who crowned themselves with the titles of philosophers and leaders have advocated as "the truth" that men are born bad and that it is the function of religion and education and the duty of teachers, priests, and political leaders to direct humanity to the right path; but if one looks at matters squarely it must be conceded that the child not only likes fair play, but often fearlessly demands justice. One of the reasons why children love fairy tales is because they have a sense of justice, which is the basis of nearly all fairy stories. Whatever may happen during the course of a fairy tale, everything turns out right in the end. The bride and groom live happy forever after; the money stolen from the hero is returned to him in the form of a hidden treasure; the princess who was killed in the attempt to save her lover is transformed into a dove and thence into a human being; the wise man who was executed because the king disapproved of his advice returns from heaven riding on a horse. These endings are all expressions of the child's sense of justice, and, to my mind, the search for justice and the love of righteousness is a strong characteristic of the normal, healthy child, which remains with him to the time he comes into contact with the superficialities of civilized life.

What is perhaps the most important, healthy children are happy by nature. The pictures on the wall, the flowers in the garden, the sun, the moon, the stars—all are sources of happiness to the child. Even little spurts of temper expressed in a stamp of the foot, in a dash of the precious toy do not last long. The fit of anger passes in a few minutes or seconds, and happiness is again restored. Children find cause for laughter at the pettiest thing—a grimace, a shrug of the shoulders, not because of the inherent fun in the object, but because the child itself bubbles over with energy and happiness.

The Psyche Changed in Sick Child

When a child falls ill, no matter how slightly ill he may be, all normal psychological characteristics either disappear or are perverted.

Fever uses up his surplus energy, so the sick child does not want to work; indeed, he cannot work if he would; since he cannot work, he also ceases to play, for, as previously stated, play to the child is but another form of work.

A sick child soon loses cognizance of its surroundings. In sickness even adults center most of their thoughts on themselves, a tendency, however, which is not so marked in adults as in children. Most children, although they do not want to be left alone when sick, cannot bear to have their parents or nurses do anything in their presence that would call for an expression of imitation; in fact, attempts to please often bore or even anger the sick child. You cannot teach a sick child. You cannot even attract its attention to anything outside of its sickness.

Although two properties, activity and imitation, are notably absent in the sick child, the power of imagination is stronger than usual and is directed along morbid channels in time of illness. The fairies give way to witches, and sunshine to storm. The child imagines he sees robbers approaching, dogs barking, horses tramping, and he feels that all of them together are contriving to do him harm. Of all the stories he has heard during his life, only fragments return during his sickness. The wise man the king has ordered killed does not reappear as an angel or dove to bring happiness to the world. The princess does not return to her lover. In effect, imagination becomes hallucination, and justice is turned into injustice.

Disease Depresses the Child

As for happiness, it is self-understood that the sick child cannot be happy. There is only one disease in which the toxin seems to exert a stimulus to make the afflicted person hopeful. Physicians and nurses who work with tuberculous people claim that tuberculous patients, as a rule, are confident that they are going to get well, and at times are even happy. However, with this one exception, disease exerts on the patient a depressing effect, which is doubly noticeable in the young. The child drops his head down on the pillow, and he does not dare to raise it; as if he were afraid that something would befall him if he did.

At times it may seem as if the patient were contented, but the expression of his face tells a different story. The happiness that lights up the face of the normal child disappears, and an expression of sadness takes its place. It is not merely pain that robs the child of his happiness; it is the sick feeling, the lack of confidence in himself, the absence of healthy imagination, and the loss of the prevailing sense of justice that robs the child of his happiness and fills him with gloom.

Practical Application

Can a knowledge of the psychology of the sick child be utilized in practice? Is it necessary for a physician or a nurse, who deal with sick children, to possess a knowledge of the psychological moods of the healthy and the sick child, and is it possible in turn to make use of this knowledge for the benefit of the child? There can be no doubt that a knowledge of the child's attitude can and should be utilized by the physician, nurse and social worker, and that without a knowledge of the psychological pecularities of both the healthy and sick child, it is hardly possible properly to attend a sick child. In dealing with a child one is confronted not only with physical ailments, but also with a complicated nervous mechanism which has not had sufficient time to stabilize itself, which has had no time as yet to tread out paths, or to form habits. The child is motivated not from stored-up energy, but from sense impressions, from imaginings, and unless it is realized that in treating sick children one is dealing with a shifting pathology which has taken the place of a constantly changing physiology; he is helpless in the face of any ailment in the child, be it pneumonia or a hangnail. The physician who knows the child from a psychological standpoint as well as a physical, the physician who can win over the child—which usually also means winning the mother and at times the grandmother—is the physician who is usually most successful, the measure of his success being more apparent in the actual results he obtains than in the routine of mere medical treatment of the child. Such a physician usually understands the responsibility placed upon his shoulders in treating children.

What is true of the physician is doubly true of the nurse. The nurse is put in charge of a sick child, not only to administer medicine, but, also, to feed the child, to make him comfortable, and to do everything she can to help him on the way to recovery. In order to obtain these results the nurse has to take the place of the mother—a very difficult position to fill; for, no matter how good the nurse may be, she will have to go far to be as good as the mother, and no matter how kind she may be, she will have to exert every effort to be as kind as the mother. The child has been given over to the care of the nurse especially because she is not the mother, and on this account can keep a clear head in case of danger, whereas the mother would be overcome by her emotions. It therefore behooves the nurse to make a study of the child's moods and habits and the changes of these moods and habits during disease. The nurse must realize that the child who acts cross and peevish during illness has not always been so. She must realize that the child who now seems too lazy to do anything for himself, and who demands that she do everything for him, at one time worked like a little beaver merely for the sake of working. She should also know that the child to whom no toys are now acceptable at one time spent hour after hour in playing with a jagged stick, a broken doll, a legless chair. The nurse must realize that the child is passing not only through a physical crisis, but also through a mental one, and she should therefore make it her duty to help the little patient pass through the ordeal before him in as quiet and peaceful a manner as possible. To be a nurse for any patient requires a great deal of patience; to be a children's nurse, one must have limitless patience, superhuman endurance, and heavenly kindness.

Must Bridge Mental Crisis

The change in the mental attitude of the sick child is doubly pronounced if the child is at the hospital. In addition to the disease itself, which tortures the little patient, several other factors add to its distress: the change of surroundings, the sight of strange faces, the shock of being away from mother and father. It is hard enough for an adult to change his mode of living in one day; how much harder is it then for a young child to be robbed all at once of his mother, who has been the only person he has known intimately all his life, and left to the mercy of a stranger whom he has never seen before. If the nurse understands the mental attitude of the sick child, she cannot help but act the part of the mother during the child's stay at the hospital. She should make the hospital atmosphere as homelike as possible; she should help the child bridge over the mental crises that confront him; she should employ all means possible to restore to the child the normal psychological functions that characterize him in time of health—activity, imagination, love for justice, and happiness.

Relation to Social Service

Just as the physician and nurse must understand the psychology of the sick child, so must the

social worker. Any attempt at relief, material or moral, made tactlessly may jar the child, may aggravate his mental attitude, and put the social worker in the undesirable class as far as the child is concerned. It is therefore, necessary for the social worker to understand the soul of the child and the mental crisis of the sick child.

The psychology of the sick child is a fertile and practical field for study. Investigation along this line will bring to light a great deal in the symptomatology and, subsequently, in the treatment of the various diseases of childhood; for there is much to indicate that each group of diseases carries with it special psychological phenomena. The study of the psychology of the sick child should make a strong appeal to every physician and nurse who is interested in the welfare of the child.

CHILD HYGIENE IN MISSOURI

On request of the acting governor, made in response to a resolution by the State Board of Health, requesting assistance in child hygiene work in the State, the United States Public Health Service is conducting a state-wide study of child hygiene problems in the State of Missouri, in cooperation with the State Board of Health and a number of volunteer organizations. The main object of the investigation is to leave behind it an effective division of child hygiene in the State Department of Health that will carry on the work which the results of the investigation indicate should be done. One of the expected results is that a number of communities throughout the State will organize at their own expense for the conservation of child life.

The work has been thoroughly coordinated with that of local and State official and unofficial health agencies.

SAFETY COUNCIL CONVENTION

The best methods of saving fingers, hands, arms, legs, and lives and of conserving labor and increasing production through accident prevention and industrial medicine will be discussed at the Ninth Annual Safety Congress of the National Safety Council at Milwaukee, September 27 to October 1, the program for which will soon be completed.

During these five days, four thousand men and women,—safety engineers, industrial relations managers, municipal traffic officers, educators and plant executives,—will gather at the Milwaukee Auditorium to throw into the common pot all the information on accident prevention that has developed during the past year.

The 1920 Safety Congress will be the most important in the history of the safety movement. One hundred and eighty speakers, each an expert in some particular line of safety work, are on the program. Accident prevention will be discussed not as a humanitarian proposition alone, but with reference to the most important industrial problems of the day,—under-production and labor unrest. Safety is no longer a haphazard proposition; it has been developed through the expenditure of millions of dollars by the industries of America and through years of research and experimentation, into a science with fundamentals as definite as those of chemistry, biology, or physics.

A special session of the Congress has been arranged where beginners in the field of organized accident prevention will be instructed in these fundamentals. This "A B C" session will be addressed by experts in the organization and operation of industrial safety departments. The Congress program includes a debate on the bonus system in safety work, between J. Claude Smith, Safety Director of the Inland Steel Company, and Philip Stremmel, Superintendent of the Hot Mills, National Enameling and Stamping Company.

PHYSICAL FITNESS OF CHILDREN

The preliminary report of the permanent Committee on Standards of Physical Fitness for Children Entering Employment, appointed by the Children's Bureau of the United States Department of Labor, is announced.

The report consists of two parts—General Recommendations and Minimum Standards of Physical Fitness for Children Entering and Working in Industry. The General recommendations advocate a minimum age of sixteen years for entrance into industry, on the ground that the period of pubescence, not completed in the majority of cases until the sixteenth year, is a time of special strain for the child. No child, according to the recommendations, should be allowed to go to work until he has had a complete physical examination, and has been declared physically fit for the particular occupation which he is about to take up. A re-examination for children when changing occupations, and periodical examinations for all working children, are deemed necessary. The need of special study by local administrative and medical officers of occupations in which children are likely to be employed is pointed out, and further scientific study of the effect of different kinds of work on the physique of boys and girls in their 'teens is declared to be essential. The fields which in the opinion of the Committee are in need of special research are listed.

The necessity for further study, states the Committee, is urgent. However, on the basis of scientific studies already made and the experience acquired in administering child labor laws prescribing physical requirements now in force in a few States, it is possible to formulate certain tentative standards. These, it is expected, will aid materially in safeguarding children from the evil results of premature and unsuitable work.

The report will be sent in mimeographed form for criticism, before being printed, to experts in industrial hygiene, State labor departments, local certificate issuing officers, and interested persons throughout the country.

The Committee consists of the following persons:

Dr. George P. Barth, Director of Hygiene, City Health Department, Milwaukee, Wis., chairman; Dr. Emma M. Appel, Employment Certificate Department, Chicago Board of Education; Dr. S. Josephine Baker, chief, Bureau of Child Hygiene, Department of Health, New York City; Dr. Taliaferro Clark, representing the United States Public Health Service; Dr. C. Ward Crampton, dean, Normal School of Physical Education, Battle Creek, Mich.; Dr. D. L. Edsall, dean, Harvard Medical School; Dr. George W. Goler, health officer, Rochester, N. Y.; Dr. Harry Linenthal, director of Industrial Clinic, Massachusetts General Hospital, Boston, Mass.; Dr. H. H. Mitchell, representing the National Child Labor Committee; Dr. Anna E. Rude, director of Hygiene Division, United States Children's Bureau; Dr. Thomas D. Wood, chairman on Health Problems and Education, Columbia University, New York City; Miss E. Nathalie Matthews, director, Industrial Division, United States Children's Bureau, secretary.

STUDIES IN PENTOSURIA

THE sugar commonly occurring in human urine is glucose. It is found in small amounts in the normal urine, its presence in larger percentage indicating an abnormal or pathological condition. The occurrence of levulose, a sugar closely related to glucose, is rare. Both glucose and levulose are chemically classed as hexoses, sugars containing six carbons in their molecules.

In isolated cases a sugar has been found which gives a reduction with the reagents commonly used for the detection of glucose in urine. This sugar, however, differs in many respects from glucose. It has five carbons in the molecule and is called a pentose. Several pentoses are known, the ones occurring most commonly in urine being aldopentoses, *i. e.*, pentoses with an aldehyde group in the molecule. They are very rarely found in nature as pentoses proper; they are, however, the building stones of high molecular polysaccharides—the pentosans. Pentoses occur in the animal organisms, forming a component part of nucleic acid. If gum arabic or if a nucleoprotein is broken down by hydrolysis, pentoses are found among the cleavage products.

The pentoses are strongly reducing and behave in this respect like glucose. There is, however, a slight difference between the reducing action of a glucose and a pentose-containing urine. The pentoses occurring in urine are in all probability in some combination with urea (Neuberg[1]), which fact may account for the slower and more spasmodic progress of the reaction.

Similar to glucose, pentosazones are formed on heating pentoses with phenylhydrazin. Pentosazones show long, slender needles under the microscope and their melting points differ quite widely from that of glucocazone. The pentoses ferment only slightly or not at all with yeast. While the properties of the osazone and the fermentation test will serve to indicate the present of a pentose, we must also make use of the fact that pentoses give very typical color reactions.

If a pentose solution is heated with Bial's[2] reagent (Orcinol-HCl-$FeCl_3$) the mixture becomes green or a flocculent precipitate of the same color may form immediately or upon cooling.

A pentose solution heated on a water bath with an equal volume of hydrochloric acid and a little phloroglucinol turns red. This reaction (Tollens[3]) is given by a galactose and glycuronic acid besides pentoses. The color produced by the latter two compounds gives a typical absorption band, between the D and E line, on spectroscopic examination. This serves to distinguish between galactose on one side and pentoses and glycuronic acid on the other. The melting points of the osazones differentiate between the latter two compounds.

Any one of the above tests used alone will not serve to prove conclusively the presence of a pentose, the only safe procedure being in the use of all, or at least the majority, of the above tests. It should be mentioned here that many filter papers contain substances which give color reactions very similar to those produced by the pentoses (Umber[4]). This fact must be borne in mind whenever filter papers are used in pentose work.

Salkowski and Jastrowitz[5] found in the urine of a morphinist a substance which, while strongly reducing, was optically inactive and would not ferment. As glucose

is optically active and fermentable, the observers investigated and found a pentose. While a number of the cases reported in the literature deal with the urines of habitual users of drugs—such as morphin, cocain, and alcohol—we find pentosuria occurring in neurotics and, also, in otherwise perfectly normal individuals. In some cases an excretion of glucose with pentose is reported.

The amount of pentose excreted is not large when compared with the sugar elimination in diabetes. It never amounts to more than about thirty-five grams per day. A concentration of more than 1 per cent is extremely rare. We shall not enter into a discussion of various forms of pentoses. The reader is referred to the work of Neuberg,[6] who was first to study the chemical nature of a urinary pentose and found it to be an arabinose. The publications of Luzzato,[7] Klercker,[8] Zerner,[9] and Levene[10] describe other forms of urinary pentoses besides discussing various interesting aspects as to their occurrence and possible formation in the body.

We have evidence of two types of pentosuria: alimentary and chronic. The alimentary type may result from the ingestion of certain fruits and vegetables which are rich in pentosans. In chronic pentosuria there is apparently no relation between the quantity and the amount of the sugar eliminated. The most commonly occurring form of urinary pentoses is an optically inactive arabinose. We must bear in mind that most all the building stones of living nature are optically active substances. This urinary arabinose is optically inactive, the excretion is apparently totally independent of the nature and carbohydrate content of the diet. There is no relation between this arabinose and the pentoses of the nuclear material of the body. From these facts there seems to be no other conclusion but that the organism of the pentosuria has the power to form this particular pentose. The work of Klercker[8] brings out a point of interest. This observer find that there is a parallelism between the hourly pentose and nitrogen elimination. As this points to a breaking down of a protein-carbohydrate complex, we are led to think of glucosamin, a compound occurring in varying amount in many proteins, because of the observation of I. Bang, who finds that glucosamin can be changed, *in vitro*, by a oxydative deamination into arabinose. However, as mentioned before, there is no conclusive evidence as to the formation of pentose in the body.

The possibility of pentosuria occurring with diabetes mellitus is indicated by some of Klercker's[8] observations, who found pentoses besides glucose in diabetic urine. Diabetes mellitus has also been known to occur in families of pentosuries. These observations are made on a few cases only and, while extremely interesting, will need much further substantiation before being conclusive. In view of the rarity of pentosuria and some of the difficulties in the quantitative identification of pentoses in the presence of glucose, the solution of this part of the problem represents undoubtedly the greatest difficulties.

PREVENTION OF SIMPLE GOITER

ANOTHER of the series of thyroid studies by Marine* and his associates in Cleveland has recently appeared. This article contains a record of an examination of the results of the prophylactic use of sodium iodid in the public schools of Akron. There are many interesting data collected, from which Marine and Kimball believe that simple goiter in man can be simply and cheaply prevented. They use sodium iodid, giving it by mouth, approximately 2 gm. over a period of two weeks, repeated twice yearly. In the mildly goiterous districts under study this dosage has prevented enlargement of the thyroid in more than 99 per cent of the children. Of 2,190 pupils taking the doses, only five have shown enlargement of the thyroid during thirty months of the study; while of 2,305 pupils not taking the prophylactic, 495 have shown enlargement. Of 1,182 pupils with thyroid enlargement at the first examination and who took the prophylactic, 773 thyroids have decreased in size; while of 1,048 pupils with thyroids who did not take prophylactic, only 145 thyroids have decreased in size. The difference in these figures is so large as to make the conclusions almost inevitable.

Marine and Kimball point particularly to the fact that in the practical application of the preventive treatment, the three periods when simple goiter occur most commonly are: (1) fetal; (2) in adolescence; and (3) during pregnancy. The prevention of goiter in mother and fetus should be a matter of responsibility of the individual physician, while the prevention of goiter in adolescent school children is really a public health measure.

THE ANNALS OF MEDICINE

THE *Annals of Medicine*† is published in the interest of American medicine under the direction of the Councilors of the American Congress on Internal Medicine and the American College of Physicians." The first number, dated April, 1920, is a good appearing magazine in which the major number of pages are devoted to a roster of the College and to abstracts of current literature. The literature abstracts are broad in scope but in many instances delayed in publication.

PHAGOCYTOSIS AND LEUKOCYTOSIS CAUSED BY LEUKOCYTIC EXTRACTS

TUNNICLUFF[1] reports that the subcutaneous injection of leukocytic extract in rabbits produces an appreciable increase in the number of leukocytes in the blood, the condition lasting from one to four days, and possessing considerably more phagocytic power than normal leukocytes. Intravenous injection of leukocytic extract produces a more rapid rise in the number of leukocytes, but is of shorter duration than that produced by subcutaneous injection. The extracts used were prepared according to the method of Hiss and Zinsser,[2]—and of Archibald and Moore.[3] Further observations were made on extracts made from horse's blood, according to the method of Hiss and Zinsser. This investigation is of importance at the present time because of the large amount of work which is being done in connection with general or nonspecific protective or immunity reactions against infec-

3. Archibald and Moore: Arch. Int. Med., 1914, xiv, 120.

tions. As leukocytosis, including phagocytosis, is one of the chief mechanisms of importance in the non-specific reactions to infections these new facts brought out by Tunnicliff should be investigated further and tested out by clinicians.

Leukocytic extract seems to be the most favorable substance yet found for producing leukocytosis. It should be recalled that the leukocytic extract as first devised by Hiss and Zinsser was thought by them to be an aid to the general but non-specific protective reaction against infection, but they considered its chief function to be to supply complement which might be lacking in a patient overwhelmed by infection, and believed that by this means they were able to obtain beneficial results in a number of cases. Notwithstanding their excellent investigation, leukocytic extract did not come into general use, and this study would suggest that their favorable results were due to the leukocytic response noted by Tunnicliff rather than to the supplying of complement. W. T.

TRANSFUSION IN BLOOD STREAM INFECTIONS

THE question of the value of transfusion in cases of bacterial infection of the blood stream is very important, and is one that cannot be answered simply since bacterial infections of the blood stream are not all the same type, and each of the several types of this condition should be treated differently. Bacterial infection of the blood stream should be called bacteriemia and is not properly designated by the obsolete terms septicemia or sepsis. Our knowledge of this condition has been obtained mostly through blood cultures, which is not a formidable laboratory procedure, and, fortunately, most laboratories are now prepared to make this examination.

What stands out as the most important discovery by means of modern blood culture studies is the error of the old belief that bacteria commonly multiply in the blood stream once they have gained entrance there. Laboratory studies have demonstrated that only in the unusual case does this occur, and that in most cases there is a bacterial focus in immediate continuity with one or a series of blood vessels feeding the bacteria into the blood stream, or else the focus is entirely within the blood stream, such as an infected thrombus in a vein or an infection of the heart valves, that is, a bacterial endocarditis. There are some cases which, because of our ignorance, are still classified under the heading idiopathic bacteriemia. In such cases we cannot discover the focus of entry or the focus of supply of the bacteria in the blood; fortunately, however, they are uncommon. It is only in these cases that bacteria apparently multiply in the blood stream. The remainder of the cases of bacteriemia fall into two groups: the temporary bacteriemia, and sustained or chronic bacteriemia. Occasionally it is possible to obtain a positive blood culture in a temporary bacteriemia and to demonstrate the transitory nature of the blood infection by subsequent negative blood cultures. This is uncommon, however, and we must look to other evidences that this condition exists even though unable at any time actually to find the bacteria in the blood. Cases of acute osteomyelitis complicated later by purulent arthritis in one or a number of distant joints in which the same organism is recovered from all foci demonstrate that the bacteria could only be so disseminated by temporary invasion of the blood stream.

There are two other important types of temporary bacteriemia. It has long been known that at its inception typhoid fever is always accompanied by a bacteriemia and that this bacteriemia always or practically always disappears in the first or the second week of the disease. More recently, however, it has been shown that a large percentage of cases of epidemic cerebrospinal meningitis have meningococci in the blood at the very beginning of the disease and that it is usual for the meningococci to disappear from the blood stream when one process becomes localized to the meninges. The exact portal of entry of typhoid bacilli and of Meningococci is not known, nor do we know if there is a primary focus of infection which for a time feeds these organisms into the blood stream. For the time being it must be considered that these organisms multiply in the blood for a while. Their early disappearance from the circulation is evidence of the difficulty bacteria have in maintaining themselves in the blood unless they are continually fed into the circulation.

Bacterial endocarditis, except in one unusual group of cases, is always accompanied by a positive blood culture, more commonly the Staphylococcus, Streptococcus hemolyticus, Streptococcus viridans, Pneumococcus, Gonococcus, or Bacillus influenzae; yet, in order for the endocarditis to occur, the bacteria must have reached the heart valves from the blood stream. It may be that only a small number of bacteria find their way into the blood and these lodge in the heart valves, or it may be that in a more severe though temporary bacteriemia only a few bacteria finding their way to the heart valves, the others being destroyed in the blood or in the spleen or other organs.

The unusual type of bacterial endocarditis in the presence of negative blood cultures is the group of cases of subacute bacterial endocarditis described by Libman[1] as bacteria free. He has brought forward evidence, obtained at autopsy, to show that some of these cases show characteristic lesions, undoubtedly caused by bacterial endocarditis. The blood cultures were negative during life and the endocardial lesions either contain no bacteria or else the bacteria are in the middle of the vegetation and covered over by fibrin which is free of bacteria.

The most important types of so-called idiopathic bacteriemia are caused by Staphylococcus aureus, Pneumococcus, and Streptococcus. These cases start as a severe, acute, infectious disease. Without a blood culture the diagnosis is not made until the appearance of multiple localized acute inflammatory lesions or petechial hemorrhages in skin or mucous membranes. Usually the portal of entry of these infections is not discovered. In cases of pneumococcemia, however, there is usually a history of a preceding mild or severe pulmonary disease. Blood cultures usually disclose great numbers of bacteria in the circulation. These cases practically always go on to a fatal termination. This group of bacteriemias, more than any other group, give the impression that bacteria actually proliferate in the blood stream. In many instances bacterial endocarditis develops, with or without the heart murmurs, and this condition is sufficient continuously to seed the blood with bacteria. As endocarditis does not always occur in the other types of cases, the evidence is admittedly in favor of actual growth of bacteria in the blood.

Bacteriemia caused by an infected thrombus in many ways constitutes the most interesting group, the one which has probably taught us most about blood stream infections, and the group which in many instances permits operative interference and often cure. The two most important types of these conditions are infected thrombosis of the sigmoid sinus, secondary to acute mastoiditis; and

1. Libman, E.: A Study of the Endocardial Lesions of Subacute Bacterial Endocarditis, Am. Jour. Med. Sc., 1912, cxliv, 313.

pelvic infected thrombophlebitis, secondary to puerperal or postabortive infection. A positive blood culture in these conditions indicates operative interference. Sometimes simply tying the internal jugular vein or the ovarian or uterine veins beyond the region of the thrombus will block bacteria from further invasion of the blood stream. At other times the sigmoid sinus will have to be opened and packed or the uterine or ovarian veins excised. If the infected thrombus is shut off from the circulation, it is remarkable how quickly the blood stream will become sterile, occurring in some cases in from one-half to one hour, a fact which affords the most complete evidence that usually the growth of bacteria is inhibited by the blood and that the blood stream tends to free itself of bacteria if the focus of infection is eliminated.

Also, positive blood cultures are obtained in some cases of puerperal infection in which macroscopic thrombi cannot be found. The exact mechanism by which bacteria find their way from the infected uterus into the blood stream is not yet known. There is one type of infected thrombophlebitis which is unaccompanied by bacteriemia. This occurs in the portal circulation, as pylephlebitis secondary to appendicitis. Here, undoubtedly, the liver blocks the bacteria against entrance in the general circulation.

Renal and vesical infections form an interesting group which can only be touched on. Severe infections in these structures are often accompanied by a high and variable temperature with frequent chill. Areas of infection occasionally develop at distant points, demonstrating that the bacteria are at times diffused through the blood stream. Great numbers of blood culture studies have been made of these conditions, but positive blood cultures are infrequently obtained, and these are usually transient bacteriemias. A recent article by Magoun[2] from the Mayo Foundation is of interest in this relation. He injected a culture of Bacillus prodigiosus into the renal pelvis of a dog under the normal pressure of the urine in the pelvis, and a number of times recovered the same organism either from the blood or from other organs. This indicates that under the conditions of this experiment bacteria from the renal pelvis can find their way into the general circulation and would explain cases of transient or sustained bacteriemia in some renal infections. Sometimes, however, in the presence of infected thrombi in the periprostatic veins, bacteria are found continuously in the blood.

Before discussing the use of blood transfusion in blood stream infection a few words should be said about other therapeutic procedures. Vaccines of any sort are contraindicated since the blood already contains great numbers of living bacteria and does not react favorably to them. Specific anti-sera for the infecting organism would be the ideal measure. Unfortunately, it has been impossible to produce potent antisera for the entire group of Gram-positive Cocci and also from many of the Gram-negative Cocci. An exception to this is the antimeningococcus serum, which has been shown to be very efficient when used intravenously. When injected subcutaneously and intravenously, foreign proteins have been shown to produce a non-specific immunity reaction. This measure has probably not been used to as large an extent as it should have been. However, a great deal cannot be expected from this. The substance which appears most logical to use is leukocytic extract, which produces a leukocytosis and also an increase in the phagocytic activity of the leukocytes.

2. Magoun, J. A. H., Jr.: Pelvis of Kidney as Possible Source for Infection of Blood Stream, Jour. Am. Med. Assn., 1920, lxxiv, 73-75.

There have been many reports of the use of transfusions of blood in cases of bacteriemia, but very few of the cases are reported as having survived or as having been cured. Disastrous results have followed the use of large transfusions. Here apparently the transfused blood has quickly killed off large numbers of bacteria, and set free bacterial toxins which overwhelmed the patient and caused death in a few hours.

The article of Polak[3] on repeated small blood transfusions in blood stream infections is, therefore, of interest. In a small number of cases of bacteriemia following puerperal infection he considers that he has obtained good results by multiple small blood transfusions. He reports four cases of pelvic thrombophlebitis with one death; and seven cases of bacteriemia not associated with throbophlebitis with one fatality. The two fatal cases were very far advanced when this treatment was started. Citrated blood was used and from 250 to 300 cc. were slowly given at each transfusion. The transfusions were repeated as indicated. Often, but not invariably, transfusion was followed by a high rise in temperature and a chill. Litigation or excision of the pelvic veins should be done when thrombophlebitis is present. If this procedure is contraindicated, or if it does not relieve the bacteriemia, Polak advocates multiple small transfusions on the basis of the favorable results noted in his small series of cases. It should be remembered that E. C. Rosenow came to the same conclusion in his studies of cases of subacute bacterial endocarditis years ago, publishing his results in the *Journal of Infections Diseases*. The procedure advised by Polak is certainly a logical one and it is hoped that it will be put into practice in other clinics, so that one may soon be able the better to judge the results from a larger series of cases.

INDUSTRIAL HYGIENE AND PUBLIC HEALTH

The interrelation between industrial medicine and the public health finds a new emphasis in subjects to be discussed in joint sessions between industrial physicians and officers of public health at the Forty-ninth Annual Meeting of the American Public Health Association, San Francisco, Calif., September 13-17, 1920. We present herewith the program of the Industrial Hygiene Section, under the chairmanship of F. D. Patterson, M.D., Harrisburg, Pa.; A. J. Lanza, M.D., Cleveland, O., vice-chairman; and C.-E. A. Winslow, M.D., New Haven, Conn., secretary.

FIRST SESSION

Tuesday, September 14, 9:00 A. M.

Honorary Chairman, E. J. Hopkins.
Secretary, C. E. Ford, M.D.
Joint Meeting with Sociological Section.
Labor Camp Sanitation: A Basis for Education in Citizenship. R. Justin Miller, Executive Officer, Commission of Immigration and Housing of California.
Health Supervision in Industry. Charles W. Crankshaw, M.D., Prudential Insurance Company, Newark, N. J.
Industrial Health Education—A Means and an End. Jules Schevitz, Oklahoma Tuberculosis Association, Oklahoma City.
Health Education in Industry. C. E. Ford, M.D., Medical Director, General Chemical Co., New York City.

SECOND SESSION

Thursday, September 16, 2:00 P. M.

Honorary Chairman, R. T. Legge, M.D.
Address of the Chairman.
Election of Nominating Committee.
A Program of Industrial Hygiene as It Touches the Employe's Home. F. A. Anderson, Social Service Director, Twin City Lines, Minneapolis, Minn.
A Plea for Physical Examination of All Applicants before Employment. J. T. Bird, M.D., Pontiac, Mich.
Hookworm Infection in California Gold Mines. Ralph W. Nauss, M.D., Dr. P.H., Colorado Fuel & Iron Company, Pueblo, Colo.
Hygienic Control of Lead Workers with Special Reference to the Blood Picture. (Stereopticon illustration.) Geo. W. Miller, M.D., LL.E., and C. Van Schaak, M.S., East Chicago, Ind.

REVIEW OF RECENT LITERATURE ON TUBERCULOSIS

By JOHN B. HAWES, 2nd, Boston, Mass.

THE amount of literature published during the past year or more on the general subject of tuberculosis is enormous. It is manifestly impossible to review or even to refer to each article on this subject; I have, therefore, confined myself to what appear to me to be the most important ones. These articles naturally fall into certain groups, chief among which are: (1) Tuberculosis and the war; (2) tuberculosis and influenza; (3) the Framingham Experiment; (4) the tuberculosis campaign, and (5) miscellaneous articles on tuberculosis.

Tuberculosis and the War

Before we entered the war alarming reports reached this country concerning the enormous amount of tuberculosis among French troops and the distressing frequency of exacerbations of this disease due to war conditions. Bushnell,[1] in a careful article, was among the first to point out the exaggeration in these statements. France apparently lost the services of nearly eighty thousand men on account of a wrong diagnosis of tuberculosis. Miller[2] confirms Bushnell's statements and gives a clear picture of what the tuberculosis problem in Europe really amounts to. Hatfield[3] reviews this subject from the American viewpoint with special reference to the soldier rejected on account of this disease. Badnel and Mendes,[4] and Maraglianc[5] describe this subject as it appears among Italian troops. Trudeau,[6] Matson,[7] Otis,[8] and Burns[9] describe the methods employed in various American camps and cantonments for the examination of troops for tuberculosis and the diagnosis of this disease. Twitchell[10] reports favorably in regard to this problem. He finds that the quiescent lesion does not tend to become active under the conditions of army life in America. Fitz and Cunningham,[11] on the other hand, report that tuberculosis was nearly three times as common among American as among British troops and that recurrences and flareups were very common among American troops shortly after going abroad. Elliott,[12] discussing errors in diagnosis, again refers to the mistakes made by the French early in the war, stating that out of eighty-six thousand troops discharged from the French army for tuberculosis later examination showed only one-fifth to be really tuberculous. Stewart[13] of the Ninette Sanatorium, Manitoba, likewise comments on this and reports that of the soldiers sent to his institution on account of tuberculosis, 28 per cent were classed as non-tuberculous. Parfitt of Gravenhurst goes so far as to say that 40 per cent of returned soldiers coming under his observation were non-tuberculous. In contrast to this, in its editorial comment the *Journal of the American Medical Association*[14] states that the War Risk Insurance Bureau has a record of more than three thousand cases of tuberculosis out of a total of 7,103 disease cases under its care. Pritchard[15] urges x-ray examination along with clinical means of detecting tuberculosis in soldiers. Bissell[16] likewise considers the x-ray of first importance. Matson[17] and Manton and Maingot,[18] in same articles, point out the limitation of the x-ray in the diagnosis of pulmonary tuberculosis. Hawes[19] goes into the details of the army tuberculosis problem as it appears in Massachusetts, and is of the opinion that the war problem is no different from the peace problem as far as tuberculosis is concerned and that the solution depends on early diagnosis, thoroughness, and utilization of all available resources, and particularly common sense. Baldwin[20] summarizes the entire subject in an excellent article. From my own experiences in this subject as consultant in lung diseases to the Public Health Service in Massachusetts and from the large numbers of men seen either at the Massachusetts General Hospital as well as privately, I should agree strongly with Elliott, Stewart, and Parfitt quoted above, that errors in diagnosis are extremely common; that any abnormal pulmonary condition is apt to be called tuberculosis; that the effects of gassing, trench and barrack bronchitis, and influenza are all often mistaken for and designated as tuberculosis.

Tuberculosis and Influenza

When the influenza epidemic first swept over this country in the fall of 1918, physicians everywhere, and particularly those whose practice dealt largely with pulmonary tuberculosis and other diseases of the lungs, began raising a very pertinent and important question as to the effects of influenza on active and inactive tuberculosis. There were two opinions in regard to this: one a small group who believed that tuberculous patients possessed a degree of immunity against this new respiratory tract disease; and another, a large group, who looked for, and who found direful results among their lung cases who had influenza. Fishberg[21] was the champion of those holding the first viewpoint. He states as follows: "I have not met a single case of phthisis during the past year which could be ascribed to have followed influenza. . . . It is not to be considered as a reactivater of dormant tuberculous lesions. . . . Tuberculous processes in the lungs have not been observed to assume an acute or progressive course after an attack of influenza. . . . The pulmonary sequelæ remaining after influenza are almost without exception non-tuberculous in character and do not require the treatment accorded to phthisical patients."

These statements, quite characteristic of Fishberg, radical in the extreme, would be approved by practically no one at present. There were not a few, including myself, who were surprised at the fact that the incidence of influenza at state institutions for consumptives was vastly less than that in other institutions for non-tuberculous patients, and who were still more pleasantly surprised at the excellent manner in which patients with pulmonary tuberculosis passed through severe attacks of influenza (Hawes[22]). We felt that a wave of needless alarm was spreading over the country and that countless errors

in diagnosis would be made and injustice done to innumerable patients should it be taken for granted that influenza necessarily reactivated and made worse a previously existing influenza. None of us, however, would for a minute agree with the extreme statements above quoted. Permin[23] states that tuberculosis is aggravated by influenza, that the tuberculous patient must be kept away from this disease, and that there will be an increase of tuberculosis following it. Berghoff[24] reports that 50 per cent of his cases showed a reactivation influenza; Stirelman[25] found that influenza did remarkably little harm to the consumptives under his care; Tewksbury,[26] in his series of sixty-four cases, feels that everyone was lighted up by influenza; Anderson and Peters[27] feel that tuberculous patients have no immunity against influenza and that numerous exacerbations are due to it. Blasco[28] is of the opinion that nearly 50 per cent of cases are made worse following influenza. Horman,[29] in his sanatorium, had only a small number of influenza cases among his patients. This he attributes to the fact that tuberculous persons possess a certain immunity against this disease. Wilson speaks of post-influenzal hemoptysis and urges that, while the patients should be followed closely, one should not be in too much of a hurry to call it tuberculosis. Recently I wrote personal letters to fifteen or twenty of the leading specialists in tuberculosis and diseases of the lungs in this country in regard to this matter. While there was a great diversity of opinion as to *how much* harm an attack of influenza did to a consumptive, there was a unanimity of opinion that it did harm and was in every case a serious complication. This is a sane way in which to regard it.

The Framingham Demonstration

This experiment, or rather, demonstration, now being carried on in Framingham, Mass., is being conducted by the National Tuberculosis Association and financed by the Metropolitan Life Insurance Company. It aims to answer the following questions: (1) Is it possible to discover and to place under adequate medical, nursing, and relief supervision all of the cases of tuberculosis, incipient and advanced, in a normal industrial community? (2) Is it possible to ascertain with some degree of definiteness the responsible social and economic factor in disease causation, including all types of morbidity, not only tuberculosis? (3) What is the most efficient utilization of the existing means available for the discovery and treatment of disease? (4) What percentage of theoretically preventable disease is practically preventable with the use of known but unused or at least uncoordinated instruments? (5) What is the best possible adjustment of social forces, existing or to be created, with the objects of the prevention of unnecessary disease and death?

The answer to these questions, as is evident at a glance, are of far reaching significance. What has been done to solve these problems, with details of methods and means employed, are described in detail by Dr. Armstrong, executive officer, and Dr. Bartlett, medical director, as well as by the Committee of the National Association in charge, in the various articles, reports, and bulletins from this group.[31 32 33]

Our Knowledge of Diagnosis

Very little that is new has been added to our knowledge of diagnosis. The fundamental principles of taking nothing for granted, thoroughness and not jumping at conclusions have been emphasized.

McCrae and Funk,[34] out of 1,200 admissions for advanced tuberculosis, found 6 per cent to be non-tuberculous. Lack of thorough examinations and neglect of sputum tests are the chief causes of mistakes. Slade[35] wisely emphasizes the fact that it is far more unjust to the patient to make an incorrect positive diagnosis than to make an incorrect negative one. His views follow closely the standards for diagnosis and treatment adopted by the National Tuberculosis Association. Philibert[36] calls attention to three valuable tests: (1) Provoked expectoration by means of expectorants; (2) injection of 50 cc. of normal salt solution and watching for a subsequent rise in temperature, two to eight hours later, and (3) temperature after exercise. Ochsner[37] places first in diagnosis the physical examination; second, a careful history. In nearly 50 per cent of cases, x-ray examination gave no help. Nicholson and Goetsch[38] describe their test to differentiate early tuberculosis from hyperthyroidism. The test depends on the constitutional sensitiveness of the patient to adrenalin. If the condition is due to hyperthyroidism he will react to adrenalin, while in tuberculosis there will be no such reaction as shown by rise in blood pressure. This test is an important addition to our knowledge on this subject.

Methods of Treatment

In treatment as well as in diagnosis nothing new has been added. Emphasis has been increasingly laid on prolonged rest; and exercise, when taken, should be standardized and carefully regulated.

Schaefer,[39] Pottenger,[40] Thompson,[41] Kinghorn,[42] and Kahn[43] describe and discuss this subject. Pneumothorax has its ardent adherents. Gammons[44] urges that it be not left to a last resort but that its use be considered in every case. Stolkind[45] advised its use in children as well as in adults. Cicconardi[46] urges its use for hemorrhage; Stirchman[47] warns of its dangers, while Parfitt and Crombe,[48] and Shortle[49] discuss its advantages and disadvantages.

Heliotherapy is coming into greater use as its value becomes known. Mills and Forster[50] describe the use of condensed reflected sunlight in laryngeal tuberculosis with good results. Collin[51] describes its use for bone and joint tuberculosis. Blegvad[52] recommends it for laryngeal tuberculosis, either direct sunlight or Finsen rays being

used. Sieria[53] calls attention to contra-indications to its use, such as fever, heart disease, nervous disposition, tendency to hemorrhage, and nephritis. Dixon,[54] speaking in regard to sanatorium treatment, calls attention to the fact that it is simply one part of treatment and that it must not be blamed if, because of its effect alone, the death rate and care incidence do not fall. What he says is of the utmost importance.

Rutledge and Crouch[55] present an excellent summary of their results with sanatorium treatment. The use of tuberculin in various forms of non-pulmonary tuberculosis continues to produce good results. As pointed out by Hawes,[56] it is of the utmost importance to remember that tuberculin is only one factor, more or less important, as the case may be. In tuberculous eye conditions, however, tuberculin seems to be of special value; of this I can bear willing testimony from numerous patients of my own, while Török,[57] Gardini,[58] and Paterson[59] confirm this opinion in regard to the treatment of tuberculous cervical adenitis. Hertz[60] urges heliotherapy for this; Dufourmentel[61] still believes surgery can produce the best results while Abbot[62] is an enthusiastic believer in tuberculin, but only casually refers to removal of tonsils. It is a pity that more emphasis is not laid in the literature on this subject upon the fundamental importance of the following:

(1) Removing foci of infection, which in most cases will be found in the tonsils, *whether* or not on macroscopic examination they appear diseased.

(2) Treat the patient who has the lumps in the neck and not the lumps alone.

(3) Use all methods of treatment at your disposal according to the needs of the individual case,—conservative surgery, tuberculin, heliotherapy, x-rays, Finsen rays, violet rays, etc.

The Campaign Against Tuberculosis

Palmer[63,64] emphasizes the fact that our campaign against tuberculosis is intimately mixed with that for public health, and urges that we broaden our campaign. Lyman[65] speaks for more cooperation; Hawes,[66] in discussing the present needs of the campaign, mentions the following as essentials: (1) Knowledge as to how much tuberculosis there is; (2) knowledge as to the existing means for handling it; and (3) cooperation. Hawes[67] describes certain methods that might be discarded and others that might well be used more than they now are. Raw,[68] Porter,[69] and Fine[70] also speak well on this subject.

Brown, Petroff and Pesquera[71] discuss the etiological factor in tuberculosis, such as dust of rooms, eating utensils, contaminated hands, saliva, kissing, tooth brushes, flies, and coughing. They conclude that kissing, or eating utensils improperly cleaned, may be dangerous factors, and that dust, flies, hands, telephone mouthpieces and properly cleaned eating utensils are not dangerous. Their investigations are of interest and importance.

RELATION OF DIET TO PELLAGRA

A study of the relation of diet to pellagra incidence in seven textile-mill communities of South Carolina in 1916, reported in *Public Health Reports*, March 19, 1920, carries the following summary and conclusions:

(1) To supplement the studies, chiefly experimental, of 1914, and 1915, a study was begun in the spring of 1916, in seven cotton mill villages of South Carolina of the relation of factors of a dietary, economic, and sanitary character to the incidence of pellagra. In the present communication the results of the first year's work with respect to the relation of household diet to pellagra incidence is reported.

(2) The selected communities were typical cotton mill "villages" and were of about the average size; none over eight hundred or less than five hundred inhabitants. Only the families of white mill operatives were included in the study.

(3) Pellagra incidence was determined by a systematic bi-weekly house to house search for cases carried on continuously from April 15, 1916, to the end of that year.

(4) Only patients with a clearly defined bilaterally symmetrical eruption were recorded as having pellagra. It is suggested that clinically, pellagra includes at least two commonly associated but etiologically essentially distinct, though closely related syndromes.

(5) Only active cases, without regard to whether they were first or recurrent attacks, were considered; the date of the appearance of the eruption was assumed to mark the onset of the attack.

(6) Data relating to household diet were secured by obtaining records of sale from the principal stores, for a fifteen-day sample period during the season immediately anterior to or coincident with the sharp seasonal rise in incidence of the disease.

(7) Comparisons of diets of nonpellagrous with those of pellagrous households revealed that the nonpellagrous enjoyed a more restricted supply of the foods of the "animal protein" group (lean meat, milk, including butter, cheese, and eggs).

(8) Increasing supplies of milk or of fresh meat were found associated, one independently of the other, with a decreasing pellagra incidence.

(9) No consistent correlation was found between carrying supplies of either (1) maize meal, (2) wheat flour, or (3) the common dried legumes, and pellagra incidence. The results of the present study offered no support for the Zeist theory of the etiology of pellagra.

(10) The potential energy in the average food supply of pellagrous households, though somewhat less than in that of nonpellagrous households, nevertheless conformed closely to accepted standards so that the fuel supply of the diet would seem in itself not to be an *essential* factor in relation to the incidence of the disease.

(11) The protein supply of the pellagrous households tended to include, on the one hand, a somewhat smaller proportion derived from animal foods and, on the other, a somewhat larger proportion from cereals and the common mature beans and peas, which would suggest that the protein mixture—amino-acid supply—in the diets of the nonpellagrous households is more likely to be physiologically adequate than that in the diets of the pellagrous groups.

(12) The proportion of calories derived from carbohydrate and fat combined is essentially identical in the supply both of pellagrous and of nonpellagrous households. The supply of carbohydrate is, if anything, somewhat smaller in the diets of the pellagrous than in those of the nonpellagrous households, so that the production of

pellagra would seem not to be dependent on the excessive consumption of this nutrient.

(13) The diets of the pellagrous households have a smaller average supply of the recognized vitamines than do those of the nonpellagrous, the disparity in supply being particularly marked with respect to the "fat soluble A" factor.

(14) The mineral make-up of the diets of the nonpellagrous households will tend to be superior to, or at least, is less likely to be deficient either as a whole or in any of its elements than that of the pellagrous households.

(15) The indications afforded by this study suggest that the pellagro-preventive power of a milk or a meat supplement is due to the effect of a correction in the type of diet studied, of a deficiency in supply either (1) of some amino-acid or acids, (2) of the ash or of some of its constituents, (3) of some as yet unknown essential (vitamine?), or (4) of all or of a combination or combinations of some of these. Conversely, they suggest that the pellagra-producing dietary fault is the result of some one or of a combination or combinations of two or more of the following factors: (1) A physiologically defective protein—(animo-acid)—supply; (2) a defective or inadequate mineral supply; (3) a deficiency in an as yet unknown dietary essential (vitamine?). The somewhat lower plane of supply both of potential energy and of protein in the diets of the pellagrous households though apparently not an essential factor, may, nevertheless, be contributory by favoring the occurrence of a deficiency in intake of some one or more of the essential dietary factors, particularly with diets having only a narrow margin of safety.

(16) The indications afforded by this study clearly point to an increase in the availability of milk, particularly by increasing cow ownership, and of fresh meat, by all year round meat markets as important practical measures of prevention and control in communities of the character studied.

Addendum: After our manuscript had gone to press there came to hand a copy of the "Report of a Committee of Inquiry Regarding the Prevalence of Pellagra among Turkish Prisoners of War" in Egypt (published February, 1919). Among the conclusions reached, the following are of most interest in the present connection:

(1) "There is no evidence of the presence of any bacterial infection standing in etiological relation to pellagra.

(2) "There is no evidence of infection by any protozoal, spirochetal, or ultramicroscopic organism standing in etiological relation to pellagra.

(3) "Pellagra is due to a deficiency in protein, as gauged by its biological value."

STUDIES IN THYMUS FUNCTION*

By ADRIEN BLEYER, M.D., Washington University School of Medicine, St. Louis, Mo.

THE experiments described in this paper were undertaken in the belief that it is possible to produce in animals, by means of removal of the thymus gland, a condition closely related to if not actually identical with rickets of human beings. This expectation seems to have been justified by statements appearing in various textbooks, Aschoff's "Pathology," for example, which reports that "Basch, Klose, and Matti have furnished proof that a scientific relationship exists between the function of thymus and the growing skeleton and that the changes consist of the most outspoken rachitic manifestations." Weil's textbook on chemical pathology states that "extirpation of the thymus in young animals is followed by marked defects in the development of the skeleton and changes in the development of sex organs. Thymus extirpation causes a loss of calcium and thymus feeding a calcium retention." He admits, however, that all results of experimental work along these lines do not harmonize, but "it is certain that deficiency in the thymus causes a defect in ossification. Also, there occurs a period of adiposity followed by cachexia with hyperplasia of the lymphatic tissues and of thyroid, pancreas, ovaries, and testes." Additional references such as these may be found in current textbooks. It appears that the work of Klose and Matti, particularly, has been most widely accepted and has been instrumental in forming opinion concerning the functions and significance of the thymus gland, but a diligent search for the details of their methods and accomplishment or any adequate presentation of their work could not be found by the authors of this paper but analysis is made of all that could be found of it as well as of all other contributions on the effects of thymus extirpation which have appeared in the literature.

The work of Restelli in Italy in 1845 was the first attempt to determine the nature of thymus function by removal of the gland. Restelli operated upon ninety-eight animals—sheep, dogs and calves—all dying within seventeen days with sepsis or pneumonia or of other causes seemingly not related to thymus. The next work was that of Friedleben which, the authors state, still remains the greatest single contribution to the subject. This was in Germany in 1858. Goats and dogs were used; some were partially and some completely thymectomized. The following data were secured from Friedleben's work:

(1) Development after partial thymectomy goes on normally in young animals; no lesions were discovered at necropsy. (2) Animals dying after complete thymectomy died of causes unrelated to the removal of the thymus. He concludes that the thymus is not essential to life.

Friedleben carried on his work to removal of the spleen simultaneously with removal of the thymus and concluded that the removal of both was always followed by death. Numerous studies were made concerning the interrelation of these two glands which it is said formed the foundation of most of the work which has followed since.

Effects on Growth Transitory

After Friedleben nothing appeared until the work of Laugerhans and Saveliew in 1893, thirty-five years later. This was performed on rabbits and dogs and all results were negative. The following year Tarulli and Lo Monaco, working with puppies, reported transitory changes in the blood, and great increase in appetite with retardation of growth, of body-weight, and of hair. The hair became coarse, lost its luster, and could be pulled out easily. A few years later the same men made another very extensive study, using puppies and chickens. The retardation of growth in weight reported in the former paper was

*An abstract of the report of Edwards A. Park, M.D., and Roy D. McClure, M.D., on "The Results of Thymus Extirpation in the Dog," published in the American Journal of the Diseases of Children, 1919, xviii, 317. Read before Pediatric Department, Washington University, March 3, 1920.

now found to be transitory, growth after a slowing-up period going on to normal. The changes in the hair as described in their former paper were confirmed. In one animal there occurred a change in color of hair from brown to white, as well as the changes in texture previously described. In one animal curvature of long bones was noted.

The work of Abelous and Billard on frogs reports that removal of the thymus was invariably followed by death within two weeks, but that life could be prolonged by thymus transplants from other animals. Vincent soon after contradicted these findings, however, and found that frogs can live quite well without thymus glands. The frog as an experimental animal in thymus work now became much used and partisans appeared on both sides of the question raised which finally appears to have been settled by Hammar who found that the removal of one or even of both lobes of the thymus produced no effect whatever upon the life expectancy of the frog. Hammar's conclusions are accepted as final and correct by Park and McClure. Then follows a long list of experiments: Adler found no change in growth or development after removal of the thymus but noted enlargement of testes and thyroid. Cozzolino in his work failed to find any variation in the texture of the hair, change in appetite or alteration in growth; but later reported a bowing of the forelegs and a swelling of the articular ends of the long bones in rabbits three months after extirpation of the thymus, death ensuing two weeks thereafter. Examination of the enlarged bones showed increased proliferation of cartilage, which extended in an irregular manner into the shaft of the bone. It was abnormally vascular, and Cozzolino suggested a relationship between thymus function and the growth of bone, and also the possibility that the changes noted might have been rachitic.

Sinnhuber now followed with calcium determinations on urine and feces of thymectomized puppies with entirely negative findings. He concluded from this that thymus removal or thymus feeding produce no change in the calcium output, and that therefore the thymus is *not* related to rickets.

Contrary findings, however, were soon reported from another source. Bracci made estimations of the calcium output and also of the calcium content of the organs in thymus containing, thymus free and thymus injected animals, and reported a very definite relationship between thymus function and calcium metabolism. Thymectomized rabbits showed great excess of calcium excretion and those injected with thymus showed a marked lowering of calcium excretion. Lastly, the calcium content of bone, brain, and blood was found much reduced in thymectomized and much increased in injected animals.

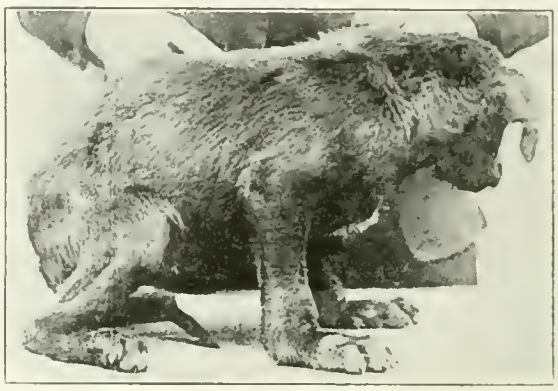

Fig. 1.—This picture shows the characteristic attitude of the thymectomized animal after the symptoms have become fully developed. It is reproduced from an article by Basch (Jahrb. f. Kinderh., 1906, lxiv, 285). The dog is obviously sick, and the posture almost certainly indicates confinement in a cage. There is nothing in the appearance of the animal to suggest rickets or any specific condition.

The thread of this contention was now taken up by Fischl, who sought to determine the activity of calcium metabolism as shown by the repair of bone. The legs of numerous animals deprived of their thymus glands were broken, and the healing process observed. No variation from that usual in normal animals could be detected. Fischl concludes that thymus function, in so far as related to the growth of bone, is nil. His experiments performed on goats and dogs were now extended to rabbits, which likewise failed to show any variation from normal; then chickens were used, with similar findings; so, as a result of his negative experiments in four different species of animals, Fischl concluded that removal of the thymus is without significance to the organism. He denied that any function whatever of the thymus had ever been shown to exist in post-fetal life and that after birth it was physiologically inert.

Fig. 2.—Side and front views of a dog, five months old, fed on a mixture of corn meal and confined in a cage from the sixth week of life. At necropsy the thymus weighed 2.8 gm. Note that the animal stands in the characteristic flatfooted posture emphasized by Basch as a typical development in animals deprived of the thymus. Note also he exhibits all the deformities described by Matti and Klose as characteristic consequences of the loss of the thymus gland. Yet the dog was never subjected to an operation. His thymus was never touched. Three other puppies of the same litter, similarly fed and confined, developed the same changes. Two of them, though remaining healthy, lost the power to stand. One control animal not confined remained normal.

This work was done in 1907 and was shortly attacked by Basch as having been unsatisfactorily carried out. High commendation is expressed for Basch's work by Park and McClure, particularly for that part of it dealing with the relationship between thymus and nervous system, published in 1908, which the authors qualify as monumental in research on internal secretion, for in it Basch established the existence of a definite and important connection between thymus function, the nervous system, and the formation of bone, and by this work

elevated the thymus to a position among the most important and best understood organs of internal secretion of the body.

A few items selected from Basch's work may be noted. First, as to bone: in a very high proportion of animals there occurred exactly similar pathologic changes in the bones, demonstrated clinically, by x-ray and necropsy. Two or three weeks after operation the bones of the extremities of thymectomized animals had become softer and more flexible, the tibias of the hind legs being first affected. These animals soon acquired a clumsy, straddling gait and became less active. Later the forelegs exhibited outward bowing and enlargement of the lower radial epiphyses and these animals began to walk with the fore feet, from the ankle downward, flat against the ground (Figs. 1-2). Growth was retarded both in height and weight and there was diminished intelligence, those most affected appearing to be quite stupid. Fracture experiments corresponded, the large, spindle-shape callus in control animals being replaced with a narrow ring formation in thymectomized animals; in two, bony union failed to occur. These differences were most marked when the thymectomy was performed in young puppies, still suckling, and the fractures made from three to four weeks after the date of operation. Earlier than this they were less marked and, when performed several months after thymectomy, were scarcely distinguishable at all. It is especially significant that after complete removal of thymus, though the occurrence of definite and uniform results were observed, these signs gradually lessened and disappeared, and were in all instances transitory. After five or six months the change induced in the skeleton by thymectomy no longer existed, and it is upon this fact, largely, that Basch placed his contention that the disturbances produced in the bones by thymectomy were not rachitic. And so it was in the matter of growth in height and weight, where the thymectomized animals in the course of time overtook or equaled their mates, the retardation of growth being temporary, as were the disturbances in the bone. The pathology of bony structure was much as described by Cozzolino, compact bone was less abundant, the marrow more spongy, the trabeculae finer and containing a great deal of cartilaginous substance; the epiphyseal line broader and more wavy, and the nuclei of ossification scattered and less advanced.

Calcium Loss After Thymectomy

Metabolism experiments were made, having to do, however, only with urine, feces being discarded. There was a definite finding, namely, that the amount of calcium in the urine of the thymectomized dogs was more than twice that of the controls, diets in each group being identical. Later experiments confirmed this, and in these the feces were included, the total calcium loss being in these greater by almost three times than in the controls.

As for the relation of thymus to nervous system, thymectomized puppies were found to develop an hyperexcitability of peripheral nerves to galvanic current stimulation, this was then found to extend to the motor areas of the brain.

From his work Basch concludes that the thymus is concerned with the growth of bone, development and calcification throughout the early period of life, and that as for nervous system, it stands related to tetany.

Soli's work now followed in agreement with that of Basch and confirmed the work of Adler showing interference with the growth of the organs of sex. As for calcium metabolism, an experiment carried out by Soli is of unusual interest. He sought to determine the activity of calcium metabolism after thymectomy by examining the eggs, and particularly the shells of the eggs, of thymectomized hens. Very commonly eggs laid after thymectomy were deprived completely of any shell and in other instances the shells, when present, were much thinner than normal.

Subsequent references add confirmations here and there, but no other new ideas were brought out. The work of Klose and Vogt is lengthily described, because it is this work which brought forward the conception of thymic idocy, thymic coma and thymic death; it will be passed over, however, because discredited by the work of Park and McClure.

Matti's work appeared in 1911, 1912, and 1913 and developed the essential fact that the removal of the thymus produces true rickets. "No finer attempt has been made to solve the problem of thymus function," is the phrase in which Park and McClure qualify Matti's work, although their own conclusions are completely at variance from his.

The Foregoing Work Checked Up

In the work of Park and McClure thymectomy was performed upon seventy-five puppies, all under seven weeks of age, and, although the work appears to center on the question as to whether rickets is or is not produced by thymectomy, interesting observations were also made on numerous other matters. (1) As to the influence of thymectomy upon the life of the animal the authors find that in the dog, at least, the function of the thymus gland is absolutely not essential to life. (2) As to the influence of thymectomy upon nutrition and growth, it is stated that no such effects as those described by other experimenters could be found in a great majority of the animals, and that a very small minority only exhibited a slowing up or retardation of growth, and that in these it was always transitory. (3) As for the influence of thymectomy on the growth of hair and teeth and on the form of the body, gait, intelligence, and appetite, no change of importance occurred. Not one of the animals exhibited any bowing of the forelegs, enlargement of joints, valgus conditions of the hind legs, atrophy of the hind quarters, or beading of ribs, as had been noted by numerous observers, nor were any deformities of the thorax noted at necropsy.

In the few instances in which any difference was noted in gait or posture it was attributed to the nature of the operation; but, to the contrary, "a dog came under our notice," they state, "which did show the identical postural abnormalities of the feet mentioned by Basch, by Klose, and by Matti as a characteristic development in thymectomized dogs and, in addition, presented marked thickening of the bones about the joints and marked bowing of the fore legs. This dog showed every deformity exhibited by the living thymectomized animals of Basch, Klose, and Matti; yet this animal was never subjected to any operation. His thymus gland was never touched. He was merely confined in a cage four by four feet for three months, beginning with the sixth week of life, and fed a mixture of meat and cornmeal." No change was noted of any disturbance of intelligence in thymectomized dogs, and the same was found concerning appetite.

Studies were made on the effect of thymectomy upon the spleen, pancreas, and organs of internal secretion. No alterations in spleen, pancreas, hypopysis, thyroid, parathyroids, or adrenals were observed which could be attributed to deprivation of thymus function. Except in two instances, the testes of thymectomized dogs showed no variations from testes of control animals. No change

in ovaries was noted. All other organs of the body were examined and found to be normal.

There remain observations on the skeleton which, although lengthily described, may be briefly summarized. As was stated, this particularly was the objective of the work in thynectomized animals.

(1) X-ray examination during life failed to show any peculiarities in the time of appearance or in the rate of growth of centers of ossification.

(2) Sections through epiphyses and epiphyso-diaphyseal junction of long bones failed to show definite disturbances or any greater inequalities of ossification than are within the normal.

(3) The length, size, thickness, and form of long bones showed no variation from bones of control animals.

From these observations the authors draw the conclusion that their "experiments yielded perfectly definite information in regard to the question of pathologic changes in the bones of thymoprivous origin and permit us to state with absolute certainty that removal of the thymus gland in the dog does *not* cause rickets or any other allied condition."

HOSPITAL OF THE MICHIGAN MUTUAL LIABILITY COMPANY

FROM all parts of the state of Michigan come the patients at the Michigan Mutual Hospital, Detroit. The hospital is operated for the treatment of men or women injured by industrial accidents in the course of their employment. The clientele of the institution are the corporations that hold policies covering industrial accidents underwritten by the Michigan Mutual Liability Company.

When it is remembered that more than two million industrial accidents are reported each year in the United States, the magnitude of the task of providing medical and surgical care for these disabled workers becomes apparent. Proper treatment of the victims of industrial accidents involves hospital problems which depend for their solution upon the institutions of the type represented by the Michigan Mutual Hospital.

Significant of the tendency toward expansion in medical service since the war is the project now receiving the consideration of the trustees and the directors of the Detroit institution. The Surgical Director of the Michigan Mutual Hospital is Lieut.-Col. Harry N. Torrey, M.C., United States Army, who spent two years with the American Expeditionary Forces in France at Base Hospital No. 17, at Dijon, and at other hospitals along the western front. With the return of Colonel Torrey, the plans now under consideration to provide for future growth will be carried into effect, and full advantage will be taken of the experience gained in the army medical service by the surgical director.

The class of cases handled by the institution, coming largely as they do from factories and industrial establishments, require treatment such as may be best described as "constructive surgery," the whole aim of the work being to return its patients to full industrial efficiency in the least possible time. The majority of cases come from Detroit and the immediate vicinity. Frequently, however, injured workmen are sent to the hospital from the most distant parts of the state.

The hospital was established by the Detroit Employers' Association for the care of their injured employees, and was acquired by the Michigan Mutual Liability Company in 1916. It is now operated exclusively for the treatment of injured employees of its policy-holding members as a part of the insurance protection afforded by the company.

The hospital was formerly one of the finest residences of an exclusive yet centrally located section of the city and because of the spacious grounds, is especially well-suited to hospital purposes.

In adapting it to hospital use a studied effort was made to retain so far as possible the home-like atmosphere and to this is ascribed a due share of the success attained in effecting prompt recoveries of serious cases.

The hospital staff comprises some of Michigan's foremost industrial surgeons, and is headed by Dr. H. N. Torrey, who has a wide reputation in this line. Associated with Dr. Torrey are Dr. G. B. M. Seager, hospital superintendent, Dr. J. H. Penix, chief surgeon, and Dr. W. A. Briegel, superintendent of the Out-Patient Department. All x-ray work is done by Dr. P. M. Hickey. The departments of ophthalmology and dental surgery are in charge of Drs. H. L. Begle and C. C. Eckfield, respectively. A masseur is in daily attendance at the hospital for the treatment of patients requiring his services.

The hospital itself contains the most modern equipment for handling the kind of work upon which it specializes. The accommodations comprise a main operating room, an x-ray room, which is also available for operations, an Out-Patient Department, for the treatment of injuries of a minor nature and for redressings, a large general kitchen and two special diet kitchens for the preparation of the special foods required for patients. The various wards and private rooms contain thirty-five beds.

A complete laundry, for the proper care of linen, clothing, etc., is operated as a part of the hospital equipment.

The hospital maintains its own ambulance and for the care of this and other cars used in the service, a garage is maintained on the premises, with a chauffeur-mechanic who is qualified to keep this part of the equipment up to the high standard demanded in every department.

To insure the best results through the Out-Patient Department a social service nurse is employed to follow up and keep under observation the cases of patients whose injuries are such a minor nature as to require only more or less frequent calls at the hospital for attention and redressing.

The hospital also serves as headquarters for the city surgical staff, members of which are located in different parts of the city, where their services are quickly available for any emergency demanding immediate attention, which may arise at the plants of members of the insurance company.

Administration quarters include a spacious reception room, a handsomely appointed dining room for the employes of the hospital, and offices for those in charge of the institution.

The personnel of the hospital includes a staff of fourteen surgeons, a head nurse, three day-nurses and one night-nurse, an orderly, two stenographers, a matron, first and second cooks and helper, a dining room girl, chauffeur, three laundry workers, and two scrub-women.

During the year ending April 30, 1919, there were handled by the hospital 497 bed cases, ambulatory cases in the Out-Patient Department totalled 7,500. Of redressings 4,708 were made in the hospital and 25,864 in the Out-Patient Department. The total treatments made by staff surgeons outside of the hospital were 61,401, making a grand total of 98,428 treatments by the surgical staff.

In 1918 there were used about one and one-half tons of gauze bandages, one ton of absorbent cotton, 12,000 yards of adhesive tape, 30,000 yards of surgeon's gauze, 18,000 ounces of iodine, 3,200 ounces of ether, 1,200 ounces of gallons of nitrous oxid, 7,500 gallons of oxygen, 3,200 Dakin's solution, besides other sundries.

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

THE NATIONAL SAFETY COUNCIL

EACH annual session of the National Safety Council brings evidence of the increasing emphasis upon health in industry as distinguished from protection against accidents. Nearly every section of the great conference of industrial leaders and experts furnished some discussions of health problems, and the Health Section itself has come to be anticipated by industrial physicians and surgeons as one of the best forums for the exchange of information, experience, and points of view. This year's program for the Conference at Milwaukee, September 27 to October 1, offers much to the growing body of industrial health specialists. Indeed, so important is the occasion that a mid-year conference of the American Association of Industrial Physicians and Surgeons has been called to meet in connection with the Health Section of the Safety Council at Milwaukee.

The recognition by the Council of the important rôle of health in the safety movement is one of the most powerful influences in forcing the industry to see the fact that sick men cause accidents and prolong the disabilities. Furthermore, it helps to spread the idea that the best kind of medical service pays in industry because it prevents infections and undue loss of time to the worker and industry.

Not alone because it prevents accidents and prolonged disabilities, does health in industry appeal to the thoughtful leaders in industry. Medicine in industry implies more than first aid to the injured. Accident prevention bears a close relation to preventive medicine and safe mechanical appliances lead to measures looking toward the general health. Safety measures protect against any disability whether incurred in the factory or outside. When a man is disabled six weeks from typhoid the loss is as serious as when he is disabled by an accident. He loses his wages; industry and society lose his production; and someone must pay the cost of his medical care. His death from typhoid leaves his dependents in even worse condition than if he were killed outright. It is fortunate that the National Safety Council recognizes the social benefits from the prevention of disease as well as accident, and thus places the movement for safety on a broad humanitarian plane instead of a selfish plane of calculation of the benefits in dollars and cents measured by the liability and compensation losses.

INDUSTRIAL PHYSICIANS MEET WITH SAFETY COUNCIL

THE officers and the Board of Directors have arranged for a midyear meeting of the American Association of Industrial Physicians and Surgeons to be held in conjunction with the Health Service Section of the National Safety Council Tuesday and Wednesday, September 28 and 29, Milwaukee, Wis. Members are urged to make their reservations at once.

The preliminary program is announced herewith. Relatively few subjects have been assigned, so that opportunity may be given for wide discussion from the floor.

The following statement is taken from an appeal sent to all members of the Association over the signature of Otto P. Geier, M.D., president, and Francis D. Patterson, M.D., secretary-treasurer, of the organization.

This meeting, occurring in the heart of an industrial section, assures the attendance of a large number of industrial physicians and surgeons. The Health Service Section of the National Safety Council has always attracted a big audience since it was first founded by the industrial physicians in 1915. The proposed joint meeting of the Health Service Section with that of our Association will add greatly to the number in attendance and afford a fine opportunity for exchange of experience.

The work of the industrial physician in the past five years has so distinctly broadened out into the field of personal relations, employment management, and safety work, that the forward looking physician will be only too glad to avail himself of attendance upon the fine program offered by the National Safety Council in connection with these various subjects throughout the week. By taking part in the discussion of these other programs the industrial physician can bring the representatives of industry to a fuller appreciation of the value of the physician in the personal relations program.

The printing of the Proceedings of the New Orleans meeting is under way, and they will be mailed to the membership at an early date.

The meeting at Milwaukee will afford the membership an opportunity of making suggestions to the officers as to the plans for the ensuing year and assist them in the preparations for the annual meeting at Boston. The Board of Directors will meet at Milwaukee to act on the suggestions made at the meeting and to complete the plans for the immediate future.

The program follows:

SEPTEMBER 28, 1920.

TUESDAY A. M.

W. Irving Clark, Jr., M.D., Chairman.

Doctor and Patient vs. Employer and Employee.
By C. C. Burlingame, M.D., Manchester, Conn.

Preventive Medicine in Industry.
By Harry E. Mock, M.D., Chicago, Ill.

The Dental Dispensary: Its Importance, Its Help, Its Cost.
By H. M. Brewer, D.D.S., Dayton, O.

SEPTEMBER 29, 1920.

WEDNESDAY A. M.

Otto P. Geier, M.D., Chairman.

The Future of Industrial Medicine and Surgery.
Address by Chairman.

Fractures Incident to Occupation.
By John J. Moorehead, M.D., New York City.

Industrial Surgery.
By William O'Neill Sherman, Pittsburgh, Pa.

WEDNESDAY P. M.

W. Irving Clark, Jr., Chairman.

Physical Examination of Employees.
By A. W. Colcord, M.D., Clairton, Pa.

Paper by W. A. Sawyer, M.D., Rochester, N. Y. (subject not reported).

EFFICIENCY OF MINE LABOR AS RELATED TO INDUSTRIAL MEDICINE

By ARTHUR L. MURRAY, Surgeon, United States Bureau of Mines Safety Car, Salt Lake City, Utah

DURING recent months much criticism as to the efficiency of mine labor has been heard from various sections of the country. No doubt much of this criticism has been well founded. The present lack of efficiency and of stability is due primarily to a spirit of restlessness and partial irresponsibility engendered during the transition from war conditions to peace time conditions. This spirit of unrest, not only among the laboring classes, but in every branch of the human family, following a period of intense nervous tension in a nation, appears to be a natural sequence of war and beyond the control of man. This condition will gradually disappear, and the majority of our people will again assume their natural order of living; but labor will for a considerable period be sensitive to these influences, whether they be exerted for good or for evil. Employers of labor should take cognizance of this fact and bend every effort towards the development of measures that promote efficiency and permanence of the working force. Labor efficiency depends upon many and varied factors. Some of these factors, as applied to mine labor, are briefly enumerated in the following paragraph:

Selection and Placement of Manpower

In the selection of men the two main considerations are physical ability and adaptability. The laws of mechanics should be applied in the selection of men, as in the selection of machinery. If a machine is required for a certain class of work, the type of machine known to be mechanically fit for such work is selected. Likewise, men should be selected with regard to their physical and temperamental fitness for the kind of work expected of them.

Every man employed by a mining company should be given a physical examination before employment. Such an examination will furnish an index by which the men may be placed in positions where they can do the work they are physically capable of. The employer and the employee are thereby mutually protected. Men with known or unknown physical defects that are not debilitating may, through being placed at work which exerts a particular strain on the parts affected, become temporarily or permanently debilitated. In many instances the employer has to pay compensation which would have been avoided had these men been placed at work not conducive to aggravating the original defects.

Records kept of pre-employment physical examinations by firms employing large numbers of men show a very low rejection rate. The physical defects found are often subject to correction, and the friendly advice given by examining physicians, when taken advantage of, frequently leads to the restoration of normal physical condition. The reports of one large corporation employing thousands of men show that on original examination 7 per cent of those applying for work were found physically unfit, but by simple operations or other corrective measures 75 per cent of those rejected on original examination were sufficiently restored to normal to warrant their employment; thus the total net rejections amounted to less than 2 per cent of all those applying for work.

Recently the author had occasion to pass upon the physical examinations of metal-mine hoisting engineers applying for certificates in the state of Utah. Among the 81 applicants the examinations showed 20 cases with defective vision, 3 cases with hernia, 4 cases with minor deformities of the limbs, and 2 cases with constitutional diseases; but only two of the applicants were rejected. All the other cases, through simple treatment or properly fitted glasses or trusses, were physically reclaimed so as to safely follow their calling.

Many men are wrongly placed at work for which they are not fitted through previous training or employment. By carefully carding at the time of employment the lines of work with which a man is familiar and has had experience, a permanent record of the working force is always at hand. The original placing of men employed can be governed by their past experience as shown by their card records. Also, if at any time men for a special line of work are required, the card records may afford an opportunity to locate the men needed among the mine force.

So far as possible, men should be selected for their stability. Frequent labor turnover is costly in many ways. The cost of breaking new men in, the disrupting of mine crews, the increased office work of opening and closing accounts, to say nothing of the effect on morale, can be measured in dollars and cents.

In the mining industry, probably to a greater extent than in any other industry, men tend to drift from one camp to another. All things being equal, a married man is more likely to become permanent and to be a greater asset to a mining camp than a single man. As a rule, a miner with a family takes his employment more seriously than a single man, has at heart the welfare of the camp, and usually will direct his influence to develop its moral tone.

Affects Industrial Relations

The successful and continuous operation of a mine is just as much dependent upon proper supervision of its manual labor as upon its mechanical equipment and technical supervision. Supervision of mine labor, if the desire is to build up an intelligent and efficient force, must be firm but sympathetic and understanding. The old type of boss, characterized by his ability to drive men rather than direct and lead them, is passing. Today we look more to intelligent leadership, technical training, and sympathetic understanding as attributes of successful supervisors of labor. Generally, workers will exert greater effort and accept direction from a man they respect and admire more readily than from a man whose chief claim to a superior position is his driving power.

Frequently dissatisfaction among miners is not towards the employing company itself, but the man directly over them is of a type that antagonizes their interests. The best results can be obtained only when mutual trust and confidence is created on the part of both employer and employee.

Supervisors with a broad viewpoint, through recognizing just complaints and through fair interpretation of those complaints to the company officials, can do much to maintain harmonious relations. Mutual regard for the well being of the employees and the economic limitations of

the employer, and the ability to equalize both factors, is one of the greatest assets to be desired in labor supervisors.

Committees on safety and committees on employees' welfare, selected among the workers, to meet and discuss problems affecting conditions in and about the mine and camp with company officials can be made the means of effecting a common viewpoint on matters of interest to all concerned. The company should be open mindedly willing to consider all matters affecting the well being of its laboring force, and use all reasonable means of promoting and enhancing such conditions.

Efficiency Through Industrial Medicine

Industrial medicine, one of the most potent means of promoting labor efficiency, has application to every branch of mining operations. In the selection and planning of camp sites, the sanitary engineer is indispensable in determining adequate water supplies; methods of drainage, including proper sewage disposal; suitable housing arrangements as regards light, ventilation, and overcrowding; and provisions for the disposal of refuse and waste. In the selection of labor, industrial medicine, as already shown, plays an important part. By careful study of working conditions, and the corrections of conditions and causes leading to accidents and illness, much needless time loss may be eliminated. Through sanitation applied to mining camps or towns and the safeguarding of the conditions under which employees live, the general health of the community is promoted. Through medical welfare work, especially by popular instruction in personal and public hygiene, much sickness, with its resultant suffering and time loss, may be prevented. The average loss of time due to illness among the workers of the United States is nine days per year, or 900 days per 100 employees—about two and one-half years. The greater part of this illness, with its time loss, is due to preventable causes.

Popular education in hygiene and preventable disease can be applied to mining communities through agencies which are not only instructive but highly interesting as well. Some of these agencies are as follows:

Visiting nurses who help care for the sick and at the same time give instruction in home sanitation, care of the ill, prevention of the spread of communicable diseases, and in personal hygiene.

Short, interesting talks on health subjects should be given at regular intervals, illustrated, when possible, by lantern slides, motion pictures, or charts. Circulars and folders are useful and, if the community supports a publication, a department devoted to the health of the worker could be established. The schools should provide courses in personal and public hygiene. Oftentimes, through interest stimulated in children at school, the adults at home are reached.

First aid classes should be organized not only among workers but also among the women and older children of the camp. Clean-up campaigns, anti-fly campaigns, etc., are useful in promoting health education and a spirit of civic betterment.

Outdoor exercise and employment during leisure hours should be encouraged through gardens and athletic grounds.

The medical and surgical care for workers should be as good as can be provided. The time loss from disabling sickness and injury can be materially lessened by prompt and efficient medical attention. Slight ailments or injuries, if promptly attended to, may be corrected with little or no loss of time; but, if neglected, they may become serious and their correction or cure entail a long period of absence from work. Men below par physically cannot be expected to measure up to par in effort. By periodic examinations a working force can be kept as near physical par as possible.

Where practical, a hospital, fully equipped, should be maintained at the mine. If no hospital is provided, there should be at least an emergency room where patients can be given emergency surgical care and made as comfortable as possible until they can with safety be removed to a hospital.

The surroundings under which a man is forced to work react on his mental attitude, and his labor output is in proportion to whether they are healthful or harmful, safe or unsafe. As men become more enlightened, their desire for better working conditions is a natural result. Hence, employers who desire intelligent and efficient men should make their working conditions as safe and wholesome as possible.

Safety, sanitation, lighting, and ventilation underground should receive proper attention and supervision. Safety devices and properly directed safety supervision more than pay their cost in decreased loss of labor through lessened accidents and saving in compensation. At large mines a safety engineer is as much a necessity as a mining engineer.

Men at work breathe more air than otherwise, and the wholesomeness of the air they breathe largely determines the amount of labor they can perform. Therefore, both as regards health and labor economy, proper ventilation of working places benefits not only the employees, but also the employer.

Drinking fountains and sanitary latrines underground are recognized necessities of large mining operations and add much to the comfort and health of the men. The general care of underground workings in respect to keeping them clean and free from débris has a marked effect on the men. The sight of débris in passageways, drifts, and tunnels encourages shiftlessness and carelessness.

Well constructed change houses where miners can bathe and change from their soiled and sweaty mine clothing to dry clean clothes before going home promotes both health and self-respect.

Above ground the general sanitary conditions about the mine should be good. Débris should not be permitted to accumulate in and about the mine entrance or about the buildings. Drainage should be such that water will not collect and stagnate. Adequate toilet facilities should be provided.

Living Conditions and Labor

As a man lives so is he liable to work. The living conditions at any mine largely determines the type of labor that seeks employment and remains at that mine. A camp where housing conditions are poor, where sanitary conditions are below standard, where the general morale has been permitted to become lax, does not attract the best element. Men who are willing to put up with such conditions are usually of the "floater" type, shiftless, lacking in responsibility, and easily influenced to find fault. At such camps agitators find fertile soil for creating dissatisfaction.

The conservation of health and the prevention of illness is one of the biggest problems faced by industry. The energy a man may expend depends directly upon his physical condition, which in turn depends upon the way and conditions under which he lives.

Housing conditions for workers, to promote their best efforts and production, should be as wholesome as they can be made. There should be no overcrowding. Living rooms should be light, well ventilated, and provided with adequate heating facilities. Houses for married workers should be attractive and of a type to encourage home making and the development of self-esteem.

Boarding houses should be kept clean and caretakers should be held to strict account for their care and cleanliness. Rigid supervision of the dining rooms and kitchens of boarding houses should be maintained. Food is one of the most important means of spreading disease, and lack of care in its preparation and serving may cause serious outbreaks of illness, which lead to a decided curtailment of production.

The food supplied at a mining camp should be good, plain, and wholesome. It should be stored and handled in just as cleanly a manner as possible.

Every mining camp should be provided with an adequate supply of pure water and every precaution should be taken to safeguard its purity.

Wherever possible, a mining camp should have a sewage system with an effluent that permits of no nuisance. If a sewage system is not practical, usually a sewage disposal system with septic tank or tanks can be installed. The general drainage should be such as to prevent the accumulation of stagnate water in or about the camp. Refuse of all kinds should be collected at regular intervals and burned. Refuse heaps are incubators for germs of disease and their distributors, filth and disease-carrying flies. Piles of cans and filth dotted over its confines detract from the appearance of a mining camp. Such conditions not only reflect upon the inhabitants of the camp, but also upon the management of the mine.

Proper supervision of the sanitary conditions of a mining camp is no small problem, but the benefit is shared by every member of the community.

Determinants of Community Influences

The social and moral tone of a mining community is the sum total of the social status and moral consciousness of its inhabitants. They are elevated or lowered in direct proportion to the predominating type of the population. Lack of regard for community influences have been costly to many employers.

Approximately one-third of a man's time is employed at his labor. Another third is usually given over to sleep. The remaining third a man seeks diversion through recreation. This spare time, through environment, may be influenced for good or for evil. Every mining camp, if it desires to progress, must recognize that wholesome and health-building facilities for recreation are a necessity.

A few of the community influences operating as an asset may well be enumerated. There should be provided: Good schools which provide for the growing generation an opportunity for education; proper medical care, with a health program and a visiting nurse; a health program which has for its purpose the prevention of sickness and the building of good sound bodies is a matter that operates for the good of all concerned; a community house where opportunity is afforded for community social gatherings is a decided advantage, and a community social program which promotes well being and provides clean, wholesome amusement for all the population. A community housing proposition which makes possible the building of homes is a most valuable means of developing a conscientious laboring force who through property ownership have a greater interest in the civic and moral welfare of the camp. Community gardens offer a means of healthful exercise in the open air and aid in reducing the cost of living. A cooperative store, which is really cooperative in function, is a great help in making a camp prosperous and its inhabitants contented. Such a store, where the profits are shared by all who patronize it in proportion to the total of their purchases, goes a long way towards reducing living costs.

Conclusions Drawn From Study

The class of labor drawn to a mining camp, whether thrifty, industrious, and stable, or shiftless, inefficient, and unstable, is largely influenced by the nature of the camp.

The wholesome or unwholesome influences of a mining camp bear a decided relation to its production.

The working forces of a mine are entitled to good living conditions, adequate water supply, sewers, light, medical care, community welfare endeavor, and facilities for healthful and wholesome recreation as a part of cost of production.

It should be the desire and the aim of every mining company to have and retain employees satisfied with the conditions under which they labor, and make their community highly desirable as a place in which to live and rear a family. The company, then, by giving can expect and should receive fair and equitable treatment from each employee.

PLANT HOSPITAL OF THE GOULDS MANUFACTURING COMPANY

By H. G. MEACHAM, Works Engineer, Seneca Falls, N. Y.

THE phase of so-called industrial welfare work commonly known as "Industrial Medicine" has much to commend it. That this fact is being realized more and more by firms throughout the entire country is evidenced

Before the Plant Hospital and Medical Department of the Goulds Manufacturing Company were established, first aid cabinets and relatively inexperienced service had proved to be inadequate.

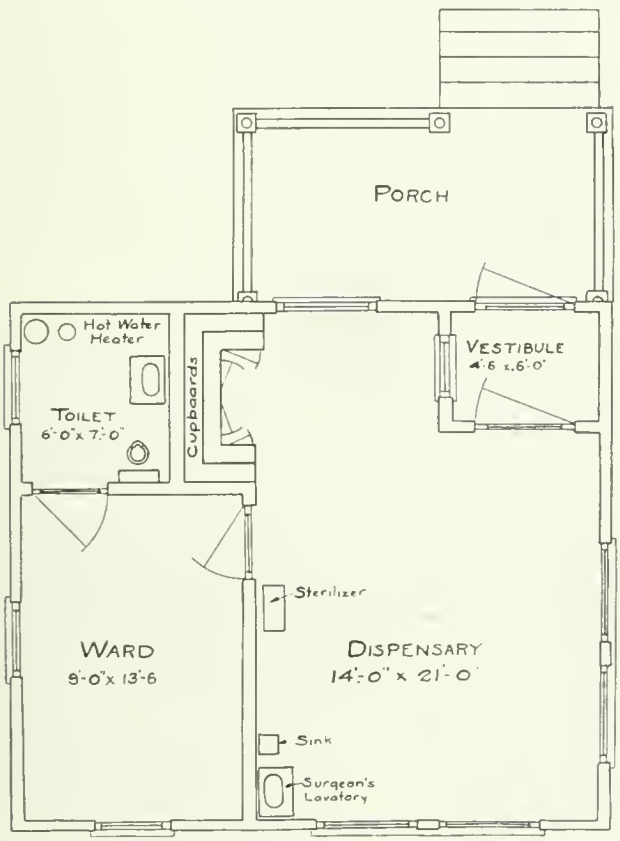
by the complete medical departments, in many cases including hospitals, to be seen in almost every plant of any size that one may visit.

A high order of industrial production demands the speedy restoration of an injured or a sick workman. This is the true function of the plant hospital: to give such medical attention to injuries or illnesses as to insure the quick recovery and early return to work of the employee so affected. Heretofore, with the crude first aid appli-

Dispensary service for minor injuries constituted the bulk of the work since the hospital was built in 1919. The building is equipped for the handling of major as well as minor work.

ances, applied with unsterile hands, many costly infections resulted, and there is no doubt that such infections caused nearly as much lost time and consequent loss of money to the worker as more serious but uninfected injuries.

These methods have been supplanted by as complete a plant hospital as one would wish to see in the plant of the Goulds Manufacturing Company, at Seneca Falls, N. Y. Seneca Falls is a manufacturing town of about eight



The hospital of the Goulds Manufacturing Company provides dispensary service for minor cases of illness as well as any severe injuries that may occur. The floor plan shows the convenient arrangement.

thousand inhabitants, having a public hospital in the village. The Goulds Manufacturing Company are manufacturers of power driven pumps and hydraulic machinery, employing about twelve hundred men. The accident rate of this plant has been very low in consideration of the fact that so many different hazards are present. Among these hazards are those of wood working, foundry work, machine shop, and structural, boiler, and electrical processes.

In the summer of 1919 the management decided to build a plant hospital and place in it the necessary equipment for the care of minor cases of illness as well as for the prompt handling of any severe injuries that might occur. The accompanying photographs will show the interior views of this building. The line drawing gives a view of the arrangement of the different rooms.

Prior to the inauguration of this medical department, the making of all accident reports devolved upon the foremen in the plant, but when the hospital was started, this work was left entirely to the head nurse, in order to relieve the foremen of a duty for which they were perhaps unfitted and which was liable to take up considerable of their time. The only form which a foreman is required to fill out at the present time is the initial order to the Medical Department to give first aid treatmen either for injury or for illness to the man whose name appears on the form. Should it be required, as is frequently the case, for the employee to return to the

The equipment and arrangement of the surgical room is shown in this picture. It is adequate to meet every demand.

hospital for a re-dressing of the injury, the nurse makes out a second form and gives it to the employee for his foreman. A third form shows the daily record of the Medical Department. In a column headed "Accident Number" is placed the number of the accident, provided it is serious enough to require the treatment of a physician, or if such an accident results in any lost time. A fourth form shows the monthly sick and accident statistical report properly tabulated and summarized.

This system of handling a plant medical department is quite simple and has worked out in a perfectly satisfactory manner. It is hard to tell just what the expense of inaugurating such a department would be, as at the present time prices fluctuate so greatly. There is no resident physician at the Gould Manufacturing plant, as the company doctor can reach the plant hospital from his office in five minutes.

NEW YORK PURCHASES RADIUM

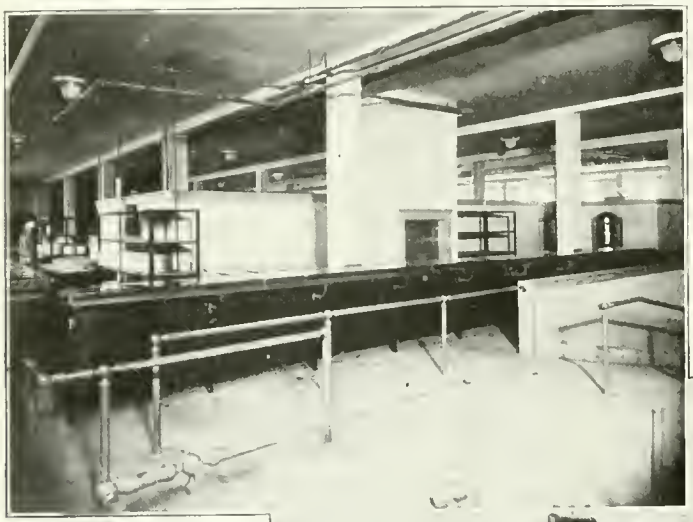
A bill introduced in New York by Senator L. W. H. Gibbs of Buffalo has been passed and signed by Governor Smith appropriating $250,000 for the purchase of radium to be held as a state asset for medical use.

THE WESTINGHOUSE LUNCH CLUB

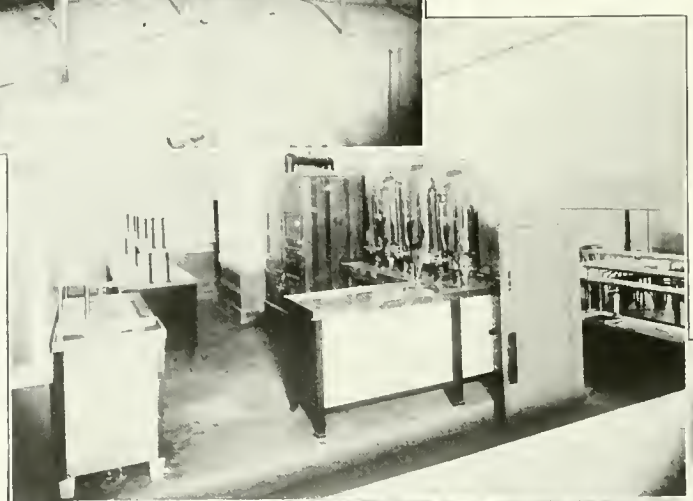
By W. W. RODGERS, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

IN recent years manufacturing plants all over the country have opened cafeterias for the benefit of their employes, who thereby are enabled to get wholesome nourishing food at very low prices and are also assured of sanitary service.

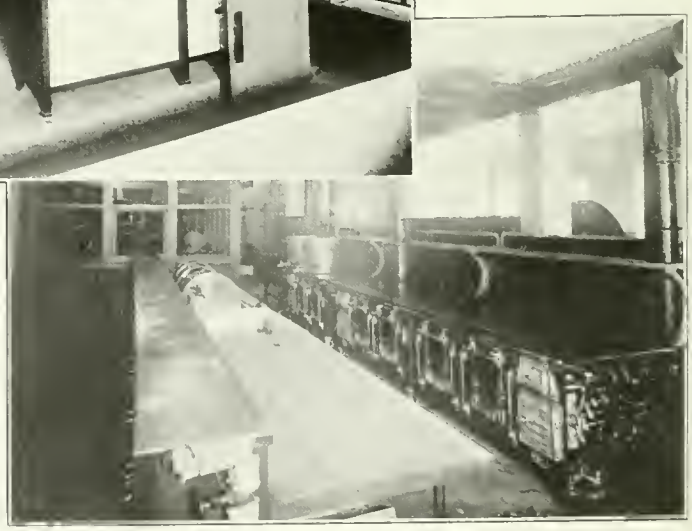
Research work had indicated that many workers are subnormal from eating unwholesome food, in many cases even the home lunches lacking the proper nutriment, and as a result they are under-nourished and are not able to handle their jobs efficiently. Complaints of this nature have been narrowed down by the establishment of company lunch rooms. Also the cafeteria plan has eliminated to a large extent the small insanitary restaurants that spring up about factories, serving lunches at low cost but in many instances preparing food unfit for use.



There are eight service counters in the cafeterias on the first and second floors. There are coffee urns, milk freezers, a refrigerating plant, motor driven washing machines and storage rooms artificially cooled.



The steam tables from which the patrons of the Westinghouse Lunch Club are served. Note the arrangement of ramp and aisles.



There are gas and combination coal and gas ranges, and electrically heated pie baker with a capacity of sixty-five pies every fifteen minutes.

Recently the Westinghouse Electric and Manufacturing Co. at East Pittsburgh, Pa., opened the largest industrial eating house in the world. The building, three stories high, has a seating capacity of more than 3,200 people and at the opening ceremonies more than 10,000 visitors were accommodated. At present the first floor is given over to women employees who carry their own lunches; a cafeteria for men and women is on the second floor; and the third is taken up with a large dining hall and an auditorium. All modern building features have been incorporated in the construction of the building, including the use of ramps instead of stairways leading to the second and third floors.

Both kitchen and dining rooms have been thoroughly equipped with sanitary, labor saving devices that enable a comparatively small force of help to serve efficiently hundreds of diners.

Included in the kitchen equipment are large gas ranges as well as combined gas and coal ranges, a steam meat roaster, steam service table, two steam heated soup kettles with a capacity of sixty gallons each, as well as a huge coffee urn for diningroom service. A potato peeler which peels forty pounds of potatoes in less than two minutes, a bread cutter and a potato masher are all electrically operated. There is also an electrically heated pie baker with a capacity of sixty-five pies every fifteen minutes. Three refrigerators—a large one for cooling meats and two smaller ones for preserving vegetables and dairy products—are also installed.

There are eight service counters in the cafeterias on the first and second floors. Up to date mechanical appliances on these floors include coffee urns, milk freezers, and sanitary drinking fountains. In addition the first floor contains a refrigerating plant, a motor-driven ice cream freezer, an ice making machine with a capacity of two thousand pounds every twelve hours, a motor-driven washing machine, mangles, and steam dryer for washing and drying the linens used by the waiters, chefs, and other help. The ice cream storage room is artificially cooled.

All food is cooked on the third floor and from there is carried to the second and first on sub-conveyers. Moving belts carry trays along in front of the main serving

tables of the cafeteria and gates at the top of the ramp leading from the street can be manipulated so as to direct the patrons to any of the serving tables as desired. This latter feature prevents too great a rush on one table at any time. All dining tables in the cafeteria have enameled tops. Tea, coffee, milk, and sugar are served free to women employees.

The auditorium on the third floor is equipped with a complete stage, footlights, stage settings, and dressing rooms. A motordriven motion picture machine of the latest type is installed in an asbestos booth in the rear of the room. The use of the auditorium, stage, or motion picture machine is given employees for any of their entertainments and dances. The hall is also utilized for lectures or other gatherings.

The Westinghouse Lunch Club houses the largest industrial eating house in the world. All modern features are incorporated in the building, including the use of ramps instead of stairways.

The lunch club is not self-sustaining but is run at a loss in order to furnish food to employees at the lowest possible rate. Since it was first opened employees of the company have responded in great numbers and by their heavy patronage have indicated to the company the need and the economic value of a lunch club of this sort in East Pittsburgh.

THE WAR RECORD OF TETANUS

By WALTER C. ALLEN, M.D., Surgeon to Rochester Works, General Electric Company, Rochester, N. Y.

AS ONE surveys the medical facts of the World War to apply the knowledge to industrial and civil practice, more progress is noted since 1914 than in all the centuries before in certain medical problems. Such a one is tetanus. Hippocrates in 460 B.C., and Galen in 130 A.D., accurately described tetanus. They had correct views as to its prognosis and considered the disease fatal. Up to 1914, even with modern surgery, nursing, and treatment with effective antispasmodics, the mortality was 80 per cent.

Progress in Prophylaxis

Since Nicolaier, 1884, discovered Bacillus tetani, and Kitasato in 1887 grew it in pure culture, the treatment of tetanus had made little progress so far as mortality statistics could demonstrate; but the prophylaxis of tetanus had made very appreciable progress, thanks in great part, to the ably directed and persistent campaign of education of the American Medical Association. Year after year, the tabulations of Fourth of July statistics published in the *Journal of the American Medical Association* showed a diminishing number of tetanus cases and fatalities. The efficiency of prophylaxis had been demonstrated so that when, in the first year of the war, tetanus developed in great numbers of the wounded, orders were issued to all armies requiring the immediate administration of antitetanic serum to all the wounded by the medical officers.

Just as brilliant medical scientists were chosen on commissions to study the war problems of pneumonia and empyema, typhus fever, trench fever, gas poisoning, TNT poisoning, shock, and the use of antiseptic, so, too, the British War Office formed the Tetanus Committee headed by Surgeon General Sir David Bruce with whom was associated Sir William Leishman, pathologist for the British Expeditionary Forces. Assigned to this Committee, among others, were Maj. F. W. Andrewes, Sir K. Goadby, Capt. F. Golla, Dr. A. T. MacConkey, Professor Sherrington, Maj. A. B. Smallman, Capt. W. J. Tulloch, and Dr. F. Ransom. The work of this Committee is recorded in the papers by members of the Committee and the memoranda published by the War Office, a list of which follows:

Andrewes, Major F. W.: On the Intrathecal Route for the Administration of Tetanus Antitoxin, *Lancet*, May 5, 1917.

Bruce, Surgeon General Sir David: Note on the Incidence of Tetanus among Wounded Soldiers, *British Medical Journal*, January 27, 1917; Importance of Early Prophylactic Injections in Trench Foot, *British Medical Journal*, January 13, 1917; Intramuscular V Intrathecal Injections, *Lancet*, May 5, 1917; First Analysis of Cases of Tetanus Treated in Home Military Hospitals from August, 1914, to August, 1915, *Lancet*, October 23, 1915; Second Analysis, From August, 1915, to July 31, 1916, *Lancet*, December 2, 1916; Third Analysis, August-October, 1916, *Lancet*, June 30, 1917; Fourth Analysis, October-December, 1916, *Lancet*, September 15, 1917; Fifth Analysis, December, 1916,-March, 1917, *Lancet*, December 22, 1917; Sixth Analysis, *British Medical Journal*, summary only, March 16, 1918; Tetanus in Home Military Hospitals—Analysis of 1,000 cases, *Transactions of Society Tropical Medicine and Hygiene*, November, 1917; Seventh, Eight, and Ninth Analysis in American Research Committee's Library.

Goadby, Sir K.: The Bacterial Flora of War Wounds, *British Medical Journal*, May 25, 1918.

Golla, Capt. F.: A Comparison of Subcutaneous with Intravenous and Intrathecal Administration of Tetanus Antitoxin in Experimental Tetanus, *Lancet*, May 5, 1917; Analysis of Recent Tetanus Statistics, *Lancet*, December 29, 1917.

MacConkey, Dr. A. T.: The Keeping Qualities of Therapeutic Serums, *Lancet*, London, January 6, 1915; The Prophylaxis of Tetanus, *British Medical Journal*, December 11, 1915.

Sherrington, Professor: Observations with Anti-tetanic Serum in the Monkey, *Lancet*, December 29, 1917.

Smallman, Maj. A. B., with Col. Sir Wm. Leishman: An Analysis of Recent Cases of Tetanus in the B. E. F., *Lancet*, July 27, 1917.

Tulloch, Capt. W. J.: Concomitant Anaerobic Infections in Tetanus, *British Medical Journal*, June 1, 1918; The Isolation and Serological Differentiation of B. Tetani, *Proc. Royal Society*, Series B., April, 1918.

Ransom, Dr. F.: A Modern View of Tetanus, *Lancet*, December 22, 1917.

The British War Office has also published the following

memoranda: Memorandum on Tetanus (Third Edition); Memorandum on the Use of Curative Sera; Anaphylaxis; and Notes on the Nursing of Cases of Tetanus.

The contributions of the British Tetanus Committee to the war history of tetanus are also recorded in a series of tables and diagrams, which will repay careful study (Tables I, II, and III).

Captain Tulloch of the Tetanus Committee made an intensive serological study of the tetanus bacillus. He found that the tetanus bacillus can be differentiated by agglutination tests, like the Pneumococci, into Types I, II, III, and IV; also, that the toxin produced by the four types is the same, and that any one of the four antitoxins will neutralize all or any of the four toxins. Mortality by groups in a series of cases showed: Type I, 11 per cent; Type II, 25 per cent; Type III, 35 per cent; Type IV, all recovered. Here again, an index of prognosis has been established and an avenue for therapeutic research along serological lines opened up.

The British Tetanus Committee, in association with Miss Robertson of the Lister Institute, Dr. McIntosh of the London Hospital, and Captain Henry of the Royal Army Medical Corps, recognizing the symbiotic affinities of Bacillus tetani, and believing that its association with B. Welchi and Vibrion septique, by withdrawing oxygen, favored the growth of B. tetani, developed a triple prophylactic serum, and sent over sixty thousand doses of it to France, but it is understood that the favorable results anticipated were not fully realized. However, studies of this phase of the problem deserve further trial. Maj. Carroll Bull of the American Army medical corps contributed to this study.

The tetanus war record of 1914-1919, as compared with the tetanus record of the wars culminating in the Battle of Waterloo, stands out like Mars at perihelion. Sir Charles Bell, it is recalled, in his diary notes on the Battle of Waterloo, describes a severe case of tetanus in a soldier of the German Legion and wrote: "There are but two cases living of all who had this affection,—this man and a French officer."

The French, like the British, from the start in 1914 concentrated tetanus cases in a special center at Lyons, France, under the direction of Prof. Léon Bérard of the Faculty of Medicine of Lyons, and Dr. Auguste Lumière.

The literature of tetanus is enriched by the record of the work of these able men. The list of their papers is appended.

Bérard and Lumière incisively detail the principles of treatment of tetanus:

(1) Débridement. All necrotic tissue must be excised, and all shell fragments or other foreign bodies and bone sequestra removed. Crystals of sodium persulphate sprinkled in the wound is an effective oxidizing agent and, therefore, inimical to the growth of tetanus bacilli and the elaboration of toxin.

(2) Toxin circulating in the blood must be neutralized by antitetanic serum.

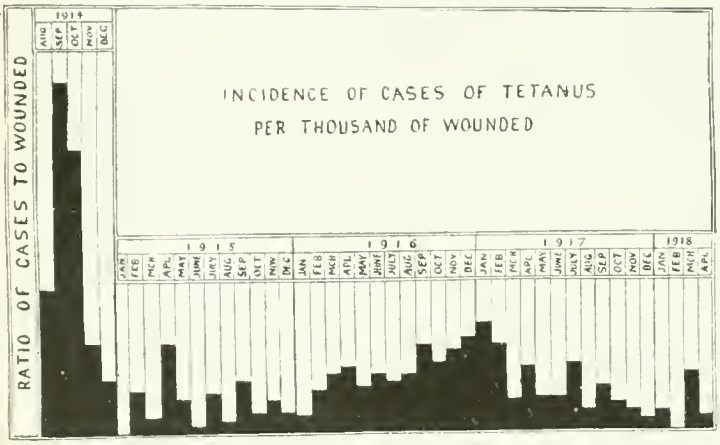
(3) Symptoms, mostly referable to the central nervous system, must be relieved. The administration of sodium persulphate is effective. To prepare this solution, five grams of sodium persulphate are dissolved in 100 cc. of sterilized distilled water. An intravenous injection of 20cc. of the 5 per cent solution is made, morning and evening, for three days. Spasm is usually immediately relieved and subsides completely after the third injection. In using sodium persulphate, care must be exercised. It is advised that a product be used in which the pure crystals have been put up in sealed glass ampules to prevent deterioration. The solution should be freshly prepared for each administration. With the use of sodium persulphate, the patients become less sensitive to external stimuli. Other sedatives, such as chloral, may be used as adjuvants to this treatment. Bérard and Lumière had no mishaps in the use of this agent.

(4) Permanent contractures are not appreciably relieved by sodium persulphate. When the contracture affects the muscles of respiration, Sauerbruck's suggestion of bilaterial phrenicotomy plus artificial respiration has been successful. Local blocking of the phrenic nerve is also available. Brachial plexi and sciatic nerves may be similarly blocked for contractures of the extremities.

Bérard and Lumière described a cerebral tetanus, a new form, thought to be a toxic manifestation, and characterized by hallucinations, delusions, phobias, noctural exacerbations, and excitation. The onset of cerebral tetanus is sudden, with maximal intensity for about a week and with gradual lessening of the severity.

These Lyons surgeons cite the case of an American soldier to illustrate the development of tardy tetanus.

TABLE I.—ANALYSES TABULATED BY BRITISH TETANUS COMMITTEE.



The British Tetanus Committee analyses of cases show the remarkable drop in tetanus cases following the introduction of the prophylactic injection of antitetanic serum, which took place about October 15, 1914.

TABLE II.—TABULATED RESULTS OF PROPHYLAXIS.

ANALYSES	N° of Cases	Recovered	Died	Mortality per cent.
1914-15.	231	98	133	57.7
1915-16.	195	99	96	49.2
Aug.-Oct. 1916	200	127	73	36.5
Oct.-Dec. 1916	100	69	31	31.0
Dec.-March 1917.	100	81	19	19.0
March-June 1917.	100	71	29	29.0
June-Sept. 1917	100	85	15	15.0
Sept.-Dec. 1917	100	84	16	16.0
Dec.-April 1917-18.	100	76	24	24.0
Total.	1226	790	436	35.5

The British Tetanus Committee studies show a reduction in mortality of more than 50 per cent and indicate that the prophylactic serum was instrumental in producing a marked attenuation of the toxin.

The soldier received a shell wound in the right scapular region. Operation for removal of the fragments was fruitless. One month later, a contracture of the right arm and pain in the neck and right shoulder developed. Massage and passive movements were started, but the patient grew worse. He was transferred to the tetanus center at Lyons. The wound was reopened, the fragments again sought and removed. Tetanus bacilli were cultivated from the fragments. Antitetanic serum was given and the patient eventually recovered.

Localized and Tardy Tetanus

The war literature is rich in case reports of both late general tetanus and late local tetanus. Cases of local tetanus are explained in part by the fact that incomplete débridement at the initial operation fails to eradicate the tetanus organisms and leaves a condition favorable to their growth. The bacilli under these conditions, it is thought, become encysted in scar tissue. The first effort to use the affected muscles, as in walking, may tear this scar tissue and liberate the tetanus bacilli so that they become reactivated. Excision of the scar plus antitetanic serum usually takes care of these local contractures. The diagnosis of local tetanus is a difficult one. Pain and contractures localized to the site of old wounds should suggest its existence.

The reactivation of tetanus bacilli is well illustrated by two cases described by Whittemore. One soldier was wounded in eleven places October 1, 1916. The wounds healed, but on March 10, 1917, trismus developed, following walking exercises. The attack cleared up only to relapse September 24, 1917. Another soldier was wounded on June 18, 1916. On April 9, 1917, trismus developed and cleared up only to relapse August 9, 1917.

When we remember that Semple, in 1891, implanted tetanus bacilli on two pens and in 1902 and 1909 succeeded in getting pure cultures from each one, one need not be surprised if tetanus bacilli persist in scar tissue.

Schellekens, who had an extensive experience with tetanus as a surgeon of the Netherlands Ambulance in France, reported many cases of localized and tardy tetanus. He cites the case of a man wounded in the lower back who was operated upon four months later for hernia, following which he developed tetanus and died. He described, also, a case similar to that of Bérard and Lumière, in which tetanus developed fifty days after a wound of the shoulder, when mechanical exercise was started. Evidently, the tearing of scar tissue reactivated the organism. Schellekens reports one case of local tetanus restricted to one side of the body and other cases in which the contracture was limited to the head or a limb.

The head tetanus of Rose, of which Williard reported several cases some years ago, is a special example of tetanus. Injuries about the face, in the presence of tetanus, are apt to be association with disturbed function throughout the distribution of the fifth cranial nerve. Facial paralysis is often seen under these circumstances. Keratitis, conjunctivitis, and iritis are frequent complications.

Ugon, in Morquio's clinic, Buenos Aires, reports a case of head tetanus in a child of twelve, developing thirteen days after receiving a cut over the malar bone with a stone. There was complete facial paralysis on that side.

Tetanus neonatorum is a form of general tetanus, prevalent in the southern states, Central America and South America. It is an index of the care of the new-born, specially in the warmer climates. Gessner, who studied the statistics of tetanus from the records of Charity Hospital, New Orleans, for the years 1908 to 1918, found twenty-five cases of tetanus neonatorum in total of 427 cases. Gomes reports 207 cases of tetanus in infants under two years out of a total of 280 deaths from tetanus in the ten-year period from 1905 to 1915, in the city of S. Paulo, Brazil. Coni reports 8,347 cases of tetanus neonatorum in a total of 10,868 cases in Argentina.

Table III.—Trismus an Index of Prognosis.

	Cases.	Recovered	Died.	Mortality per cent.
A Trismus the earliest symptom.				
(1) With complete closure of jaws developing within 24 hours after onset of symptoms	17	7	10	58.7
(2) With complete closure of jaws, developing after 24 hours	19	14	5	26.2
(3) With incomplete closure of jaws	111	85	26	23.4
B, Trismus occurring after other symptoms of tetanus have shown themselves	57	49	11	19.2
C General tetanus without trismus	19	19	3	15.7
D Local tetanus	77	77	0	0

The British Tetanus Committee study of trismus shows that it is a valuable index of prognosis. It is also interesting to note that all of the twenty-seven cases of local tetanus recovered.

Determination of Dosage

The data as to the efficacy of antitetanic serum in prophylaxis and therapeutics rest upon empirical grounds. This explains the furore over the dosage of diphtheria antitoxin. In the absence of exact data, the dictum, "Give enough," should guide one. Bezy thinks from 2 to 4 cc. of serum will give protection, but the consensus of opinion favors 1,500 units. The French, British, and American armies used 1,500 unit doses for prophylaxis.

Tizzoni, Bologne, noted in the 1914 and 1915 campaigns in France an incidence of tetanus among wounded Italian troops, most of whom had received prophylactic serum, of 0.5-2.5, or 5 per cent. He suspected the dose to be insufficient. He experimented on animals and developed the fact that ten times what had been regarded as the maximum prophylactic dose could be administered. Subsequently, 40,000 gravely wounded Italian troops received the heroic prophylactic dose of 15,000 units. Only eleven cases of tetanus developed in these 40,000 wounded. Four of the eleven died. Three of the four lay in No Man's Land from one to three days before receiving the prophylactic serum; so only one fatal case of tetanus remained unexplained. Ochsner of Chicago has adopted the massive prophylactic dose for use in his clinic at Augustana Hospital.

The subcutaneous administration of serum is favored for treatment as being the safest procedure. Serum into vein, muscle, or subarachnoid space is also administered

and sometimes it is administered in combination of two or more routes. Therapeutic doses of 30,000 units, repeated daily, are usually given; but doses of from 50,000 to 500,000 units are frequently administered. Here, too, the dictum, "Give enough," must govern dosage. The prophylactic serum confers immunity for seven to fourteen days at the most, so that during the war the practice of giving four doses of the prophylactic serum at seven day intervals was adopted, as was also the administration of a prophylactic dose immediately before delayed operations on the wounded.

Inasmuch as the immunity conferred was incomplete as had been clearly demonstrated through the development of local and tardy tetanus in those who had had prophylatic serum at the time of injury, Bezy proposed to complete it by vaccination. He used as vaccine an iodized toxin. This toxin corresponded to that used at Institut Pasteur to prepare the horses providing serum. This toxin was of a strength such that 0.0001 cc. sufficed to kill a guinea pig of 400 grams. A mixture of two-thirds toxin and one-third iodized solution (iodin 1 gm., iodid of potassium 2 gm., distilled water 200 gm.) gave a liquid effective for vaccination. Bezy injected 4 cc., 8 cc., and 12 cc. at intervals in much the same way that typhoid vaccination is effected. There were neither local nor general reactions.

London and Aristovsky, in 1917, working in the Institute of Experimental Medicine, Petrograd, reported that they had succeeded in obtaining tetanus toxin and digestive ferments, carrying them down by colloids. Ammonium sulphate in 17 per cent solution was added to the culture fluid of tetanus bacilli and centrifuged. The sediment was washed with 3 per cent ammonium sulphate solution. The sediment, after centrifuging, contained tetanus toxin. It was dried and then rinsed repeatedly with ammonium sulphate. The dried toxin was of a strength such that 0.00000002 gm. was fatal to white mice two days after injection. Such a toxin would make it possible to develop a standardized product from which vaccines could be prepared and administered by methods such as proposed by Bezy. It would also seem possible to develop tetanus lipovaccines along lines advocated by Russell for typhoid vaccination.

Komayashi has submitted experimental data, indicating that antitetanic serum administered within twenty-four hours of the injection of toxin protects, while serum administered after forty-eight hours of injection of toxin is ineffective, all of which again emphasizes the importance of very early administration of prophylactic serum. His work also indicates that a quantity of antitoxin sufficient to neutralize the available toxin in a given case was effective in the proportion of one by subarachnoid route, ten by intravenous route, three hundred by subcutaneous route; that is to say, three hundred times as much antitoxin would he needed, for subcutaneous injection as would be needed for subarachnoid injection. This work was performed on guinea pigs.

Tetanus, as an incident of Fourth of July celebrations has been well nigh eradicated. It now remains for industrial surgeons to eliminate it as an element in their practice by the more general use of the prophylactic serum. The danger of tetanus is especially great where new construction is going on, as unremoved nails in discarded lumber are responsible for a large number of puncture wounds of the feet.

TELLURIUM A HAZARD IN INDUSTRY

A preliminary account appears in the *Public Health Reports* for April 16, 1920, of the importance of Tellurium as a health hazard in industry. The report is prepared by Marvin D. Shie, M.D., assistant surgeon, and Forrest E. Deeds, scientific assistant, United States Public Health Service. The effects of tellurium are thus summarized:

The tellurium poisoning encountered thus far in industry has not been severe. The primary effects are suppression of the sweat, of the saliva, and of the acid in the gastric juice. This leads to a dry, itching skin, dry mouth, metallic taste, anorexia, nausea, vomiting, indigestion and constipation. Somnolence is often a prominent symptom, The earliest symptom of tellurium absorption is the garlic odor to the secretions and excretions due to methyl telluride. Secondary effects to be expected are impaired nutrition with emaciation and where the workers are exposed to high temperatures, increased susceptibility to heat exhaustion.

The diagnosis of tellurium poisoning may be made from the garlic odor of the excretions, the suppression of the sweat, the dryness of the mouth, and the demonstration of tellurium in the urine or feces.

The preventive measures are similar to those used for other metallic poisons and may be summed up as good working conditions and proper personal hygiene.

In treatment, of course, the most important measure is the removal of cause. After that pilocarpin may be used to counteract the effect of the tellurium; the avenues of elimination should be opened and excretion favored by promoting secretions, diuresis, and free bowel movements. Hydrochloric acid may be administered to remedy the deficiency of acid secretion. The remainder of the treatment is symptomatic. The prognosis so far has been good, the condition gradually improving upon prompt removal of the cause.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

THE CAMPAIGN AGAINST INFANT MORTALITY

THE campaign against infant mortality which began in France with the establishment of the first *gouttes de lait* twenty years ago has broadened out to include a comprehensive program of health supervision which extends from before birth to the date of entrance into school.

From the organization of the American Association for Study and Prevention of Infant Mortality in 1909, the "milk station" rapidly developed into the "babies' dispensary"—its objective being the systematic supervision of the health of the infant and the instruction of the mother in the essentials of infant hygiene, with the public health nurse as a home visitor supplementing the more formal teaching of the clinic itself. The results attained by this kind of health education have been almost spectacular in nature,—the reduction in a period of thirty years of the infant mortality rate of New York City from 227 deaths under one year per one thousand births to 92 deaths per one thousand births being only an extreme instance out of hundreds of similar ones which might be cited.

During the last few years, however, we have realized that the brilliant success which has been achieved in the reduction of infant mortality was limited to certain causes of death, while other factors in the infant death rates have remained untouched. In almost any series of mortality rates a high infant mortality rate always implies a high incidence of diarrhea and enteritis. Heredity, prenatal care, poverty—all are important factors. Education plays an important rôle. The data cited below from a recent report of the United States Census on Mortality Statistics for 1918 bring out with clearness the contrast between our successes and failures.

A STUDY IN INFANT MORTALITY

Infant Deaths from Certain Causes per 1,000 Population Under One Year of Age, United States Registration Area.

	1910	1911	1912	1913	1914	1915	1916	1917	1918
Diarrhea and Enteritis	37.7	29.0	26.2	28.1	24.7	22.6	24.1	23.2	22.2
Malnutrition	6.6	6.4	6.5	6.8	7.3	6.9	7.5	7.5	7.5
Premature Birth	17.5	18.4	19.1	20.0	20.1	20.3	21.2	21.1	22.1
Congenital Debility	13.2	14.6	15.0	15.5	13.4	11.9	10.3	9.4	10.1
Injuries at Birth	3.2	3.7	3.7	3.9	4.2	4.3	4.4	4.6	3.9
Sum of Above	40.5	43.1	44.3	46.2	45.0	43.4	43.4	42.6	43.6

The death rate from diarrhea and enteritis has been reduced from an average of 31.0 for 1910-12 to an average of 23.2 for 1916-18, a saving of 7.8 lives per one thousand. On the other hand, the combined death rate from malnutrition, premature birth, congenital debility, and injuries at birth, has increased from an average of 42.6 for 1910-12 to an average of 43.2 for 1916-18. The intestinal disorders, which prevail for the most part from the third month of life, are yielding to preventive measures but the causes of mortality which operate at birth and during the first month have continued to operate unchecked.

It is this fact which has made it clear that the machinery of medical examination and hygenic supervision must be extended backward to include the expectant mother, and the experience of the prenatal clinics in Boston and New York have shown that the mortality of the first month is quite as amenable to preventive measures as that of the later months of infant life. The ratio of still births to living births has been reduced in Boston to 1.0 per cent for cases with prenatal care, as compared with 3.4 per cent for the population as a whole; and the mortality of infants in the first two weeks of life has been reduced to 11.9 per cent as compared with 34.2 per cent for the population as a whole.

In order to cope with the broader problems of the present and future campaigns against infant mortality, the Association for Study and Prevention of Infant Mortality has changed its name to the American Child Hygiene Association and, under the able presidency of Dr. Philip Van Ingen, is entering upon a corresponding extended field of service. In June it issued the first number of a new monthly magazine, *Mother and Child*, which we welcome most heartly to the ranks of public health journalism. This first issue contains papers of great value by Sir Arthur Newsholme and Dr. F. L. Adair on the development of prenatal work in England and France, and a discussion by Dr. R. D. Curtis of the supervision of that neglected twilight zone of childhood, the "pre-school" age. In the same batch of mail which brought this new journal is Bulletin Number 69 of the Children's Bureau on "The Child Welfare Special," describing the latest technic in reaching the rural mother and child by means of a child welfare motor truck and a pamphlet issued by the Association for Improving the Condition of the Poor of New York City, entitled "Developing Child Health Via Community Organization," which outlines the admirable program carried out in two selected tenement districts for prenatal care of the expectant mother, and for the examination and supervision of the child of pre-school age.

We stand on the threshold of a new era in child hygiene; and we may confidently look forward to the development within the next few years of a complete and coordinated program of medical supervision and health education, which shall begin with the unborn babe and shall end only when the child passes from school into the world of practical achievement, with the fullest perfection of development and the fullest reserve of physical health and power within the possibilities of its inherited capacity.

EDITOR.

MEMORANDUM ON MALNUTRITION

By I. A. GOLDSTON, M.D., Assistant Director of Health for the Community Councils of New York, New York City

Much of the mystery of medicine which has in the past centered about the processes of metabolism has been cleared up by painstaking laboratory analyses, and the necessary chemical constituents of food have been fairly well worked out.

Getting a right régime carried out, however, is a more difficult matter. Scientific knowledge is available on the one hand. The problem remains, on the other, to break up the association in the popular mind which pairs off malnutrition with poverty instead of with organic disorder or bad food habits.

The remedy in most cases is not more food, but food better prepared and more nicely adapted to individual needs; and, as in other exigencies of the present time, the method of applying the remedy lies in training,—more training for the whole people in the fundamentals of health.

PRELIMINARY to any consideration of malnutrition it must be stated that the problem is very intricate and difficult. This almost platitudinous observation is warranted in the light of experience. Too many are the people who enthusiastically turn to the problem and who, unwarned of the difficulties confronting them, are too soon discouraged. Too many are the sporadic and fruitless attempts at solution in brief of a problem that is extensive and whose etiologic factors are manifold. It were wiser by far, and certainly more economical, to survey the field at first and to become acquainted with its various phases. It were wiser by far to be forewarned of all the difficulties and to prepare for a long and laborious task. For in the last analysis the solution of the problem of malnutrition is intimately associated with the solution of all community-wide disease problems and with the functional development of preventive medicine. Not until the general public is sufficiently educated in matters of health and hygiene to be able intelligently to think of food in terms of fuel, and of the body in terms of a physicochemical engine; not until the general public is untaught its thousand superstitions; and not until the common intelligence of the entire community is applied to this community problem, is there hope of eradicating the condition of malnutrition.

Insufficiency Not Malnutrition

Malnutrition does not invariably indicate insufficiency of food. Yet among the laity such is its common interpretation. By an interesting mental association of terms nutrition brings to mind food, and malnutrition brings to mind insufficient food. The train of thought then is switched from insufficient food to poverty, and poverty stirs up the very human emotions of pity and charity. Thus all scientific consideration of the problem is made impossible and people who attack the problem, with excellent intentions, come out of the process philanthropists.

Malnutrition in its simplest sense implies a condition in which the intake and absorption of nutriment are either insufficient in quantity or so poor in quality as to fail in supplying a sufficiency of the required elements for normal growth and function.

A.—The causes of malnutrition may be:
1. Insufficient food (gross bulk).
2. Poor mixture of foods.
3. Lack of "live" foods, *i. e.*, salt and mineral containing foods.

These three may be considered the exogenous factors, and of these the second and third are the important ones. True, in certain of the poorer sections of the city there are ill nourished children whose condition is due to insufficient food, but these children constitute only a small percentage of the total The greater number of sufferers may trace the cause of their condition to an unintelligent mixture of foods, and to the predominance in their diet of vitiated, preserved, and treated articles of food.

B.—In addition to the exogenous factors there are certain endogenous ones; these are related to the vital, mechanochemical process of the preparation and distribution of the nutriment elements for cellular use. The endogenous factors are too numerous and of too technical a nature to render possible their complete enumeration here. Such an enumeration is not essential to our present purpose, but they may all be included under, and expressed by the term "Organic and functional malconditions." Among the principal ones may be enumerated:
1. Bad teeth.
2. Nervousness.
3. Impaired respiration.
4. Cardiac derangements.
5. Gastric derangements.

C.—Still further may be enumerated certain factors neither truly exogenous nor endogenous, such as:
1. Irregular feeding.
2. Insufficient rest, etc.

These three large groups of etiologic factors—A, B, and C—may be taken as the chief causative agents of malnutrition, and as such must serve as the points upon which remedial activities must concentrate. Since there is no hope for a complete and permanent cure of any malcondition save in the removal of that malcondition's causative forces, whether that malcondition be an individual disease or a social discord, there is no hope of a solution of the problem of malnutrition save in so far as its etiologic factors are removed. We must, therefore, review the causes enumerated and see how each of these may be treated.

Exogenous Factors of Malnutrition

(1) *Insufficient food (gross bulk).*—This is primarily due to insufficient family income, and hence is part of a problem in social economics. For the solution of this difficulty there is needed, immediately, a minimum wage that will guarantee a standard of living to the worker and his or her family, and ultimately a more equitable distribution of wealth in the form of wages that nearer approximate values produced. Properly viewed, this form of malnutrition is secondary to an economic malcondition, and should be treated as part of the primary and greater problem.

(2) *Poor mixture of foods.*—This is due, of course, to ignorance of dietetic facts and laws. For this problem education is the solution: education in dietetics, not in terms of calories, but in the broader terms of physiology. This education should begin in the public school, and should be extended as a community movement. By or-

ganizing classes composed of the women members of the councils, and which are under the supervision of a single or a group of the district physicians, weekly sessions may be held during which the nutritive values of various articles of food and ideal menus can be discussed and considered. Food values in terms of costs, too, might be discussed, the services of domestic scientists being engaged for such periods.

On this topic two points of importance must be noted: (a) Most of malnutrition is due to an unbalanced diet, the diet being sufficient in bulk, but improperly made up; and (b) in these days of the H. C. L. the cost factor of foods becomes important and the overcoming of the evils of an unbalanced diet may be linked up with the equally important matter of learning the nutritive values of foods in terms of dollars and cents.

(3) *Lack of live foods.*—Malnutrition due to the lack of "live" foods is really a special division of Section 2. In this last condition we may have a diet balanced as to carbohydrates, fats, and proteins, but devoid of those essential growth-stimulating elements which the scientists, for want of better name or knowledge of, have called "vitamines." These protein, growth-stimulating elements which have but recently come into scientific prominence, like most nitrogen compounds, are very unstable and are destroyed when the foods containing them are subjected to the various preserving processes and agents. Unless, therefore, a diet, in addition to being balanced, also contains a sufficient quantity of these "living" foods, its effects will be the same as, and under certain conditions more serious than, the effects of an unbalanced diet.

The remedy for this form of malnutrition, as for the above, is dietetic education; education, it is to be repeated, not so much of a theoretic as of a practical nature.

Endogenous Factors Considered

The endogenous factors of malnutrition, grouped as they are under the heading of "organic and functional malconditions," point to the extensive and unattended need for medical treatment. More immediately these factors indicate the need of thoroughgoing physical examination of the young, both of school and pre-school age. This examination should be both thoroughgoing and periodic, and should be followed by proper medical, dental or surgical treatment, wherever and whenever these are indicated. For this function the citizen groups should in an organized and constructive manner bring pressure to bear upon their local governments to provide for an extension and improvement of the present school medical services. It is proverbial that in the United States more is spent on health for pigs than for babies.

One very important item among the endogenous factors is bad teeth.

(1) On this item we must note the existence of a vicious circle of interplay between exogenous and endogenous factors, all converging toward the ultimate of lowering of the vital power of the organism. Thus bad teeth mean poor digestion; poor digestion, through a series of results, leads to poor teeth, and so on. In fact, it may be said very definitely that the various factors enumerated are treated categorically only for the convenience of so handling them. They are, in truth and in reality, not so distinctive. Nor is it in every case possible to tell whether bad teeth, nervousness, or gastric derangement gave rise to a condition of malnutrition or malnutrition gave rise to bad teeth or nervousness or gastric derangement.

A type of dental treatment made use of in certain of our neighboring states, but not employed to any extent in our schools, is dental prophylaxis. This treatment is preventive, pure and simple. It aims at preventing the conditions favoring decay. Technicians, trained in dental prophylaxis, periodically examine and clean the teeth of the school children, removing the accumulated debris and tartar, and cleaning away all stains and discolorations. Since these technicians need not be dentists, their services usually are not costly, but are most valuable.

(2) What has been said at the head of this chapter and under bad teeth may in a general way be held true for all the other enumerated endogenous factors, save that nervousness needs such particular treatment as is aimed at a cure of the abnormal irritability. For this group of sufferers extra classes should be formed in which special attention can be given to them. The curriculum must be modified, periods of rest must be included in the day's session, and in a general way treatment must conform to individual needs.

So, too, impaired respiration, commonly due to adenoids, enlarged tonsils, hypertrophied turbinates, or deflected septum, demands surgical treatment, and cardiac and digestive derangements require particular curative treatment.

Irregular feeding and insufficient rest so plainly indicate their relations to malnutrition and so clearly point to their treatment that little space needs to be given to them in this memorandum. However, attention should be called to their importance. It is a vicious habit, which many school children develop, of bolting their luncheons and rushing to the school yard for a remaining half hour's break-neck playing. To play is certainly good for the growing child, but the time element is important and should be considered. Following luncheon should come a period of rest during which digestion may be carried on *sans* disturbance. As it is, the playing draws the blood away from the alimentary system to the regions of extra muscular activity, with the result that fatigue is increased, and the food is but slowly and poorly digested.

Summary and Conclusion

The analytical enumeration of the various etiologic factors of malnutrition is of value (1) in the orientation it makes possible and, (2) in the clarity with which such an enumeration points at the proper mode of attacking the problem.

From the above analysis it is hoped it will be seen that the problem of malnutrition is very complex and that no single procedure can, therefore, prove remedial in the fuller sense. In fact, since the problem of malnutrition is seen to be so intimately associated with the many other contemporary social problems, no hope may reasonably be entertained for the complete eradication of the condition before our social organization has progressed so far as to have intelligently eliminated all those pressing malconditions which so seriously strain our social fabric.

However, there are certain paths of action that may be followed to advantage in the treatment of a problem of malnutrition. The first of these is education: specific and general health education.

The socialization of knowledge is the first ingredient of a true panacea. The other ingredient is a conscious and intelligent pursuit of the ends so pointed out. People must know, and their education on the matters of health should begin in the public school and should be extended through all of school life and further. To the three R's, without the possession of which no man may be deemed even rudimentally educated, should be added the fourth R—standing for the Rules of Health, and the last should be as firmly insisted upon as the first. The community organizations here may prove efficient instruments. Not

only can they serve immediately as educating agents conducting open forums for the instruction of their mature members; but also they can bring pressure to bear upon the proper sources, with an aim toward modifying the curriculum to include a more extensive study of hygiene than is given at present.

Another important line of activity is the extension of municipal health activities. Health is a community problem best dealt with by the community through its own machinery. Health is not a private matter. The various departments of the Board of Health should, therefore, be urged to broaden and deepen their scopes of activity, especially in those treating the young.

And, lastly, local experiments should be conducted wherever the required facilities exist or can be brought into being. These experiments, of course, for the present can prove no more than palliative in effect; but they are precious in the facts upon the treatment of malnutrition which they indirectly bring to light.

TYPHOID FEVER AND ITS SOURCES IN MASSACHUSETTS

By STANLEY H. OSBORN, M.D., C.P.H., Director, Bureau of Preventable Diseases, Connecticut State Department of Health, Hartford, Conn.

THERE were 2,007 cases of typhoid fever reported in Massachusetts during the two years 1918 and 1919; of this number 158 cases were fatal in 1918, giving a death rate of 4.0 per one hundred thousand; and 1919 there were 103 deaths, which established the remarkable death rate of 2.6 deaths per one hundred thousand. This is the lowest rate that any state has reported up to the present time for this disease. Very few persons ten years ago expected to see a state death rate from typhoid fever less than that of measles, scarlet fever, or whooping-cough; but in Massachusetts there were fewer deaths from typhoid fever in 1919 than any of those diseases. (Table I.)

There were investigated in 1918, 752 of the 1,067 typhoid cases reported; and in 1919, 913 cases were investigated of the 940 cases reported.

These cases were investigated by the more efficient boards of health, the state district health officers, and the epidemiologist. The data collected are interesting, because they indicate the source of infection of typhoid cases in a state with a temperate climate, where the larger communities are furnished with good water supplies and sewage disposal systems. A study of the data obtained is given on this and the following pages (Table II).

Of the 1,665 cases on which data were collected the source of infection was found in 21.8 per cent of the cases in 1918 and in 30.5 per cent in 1919; or, for the two years, 26.6 per cent. It serves to indicate what investigation of the individual cases will bring forth.

The Several Sources Searched

Water.—The drinking of polluted water has been but a slight factor in recent years in the incidence of typhoid; but during 1919, 38 cases were apparently infected by a municipal supply, 18 cases by a polluted spring, and two outbreaks of 13 and 6 cases each, by a polluted well. In each epidemic large numbers of bacillus coli were found in the water. The remaining 5 cases were infected by polluted water when on visits to Maine and Canada.

Milk.—In 1918 one outbreak of 6 cases on a milk route was due to milk infected by a clinical case, and 48 cases were caused by milk infected by a carrier. In 1919, milk infected by typhoid bacilli carriers caused 56 cases of typhoid, 3 of which were infected in New Hampshire.

Food.—Food, other than milk, is undoubtedly one of the chief factors in causing typhoid fever, because the typhoid bacilli carrier in handling food, infects it, and one which accounts for sporadic cases occurring here and there in isolated parts of communities. During 1919 a food outbreak of ten cases occurred, but the suspected carrier was not confirmed by bacteriological tests, although a positive Widal test was obtained.

Probably 50 per cent of the "endemic" typhoid in Massachusetts is caused by food infected by a carrier, particularly by carriers in households, restaurants, hotels, and similar places.

Contact with Clinical Cases

There were 221 cases, or 13.3 per cent of those investigated in 1918 and 1919, who had been in contact with clinical typhoid cases. The great factor in contact, however, is contact with a typhoid bacilli carrier, which has been discussed under "Food."

The part played by flies as agents in the spread of

Unknown source of infection	688	634	1,222	73.4
Totals	762	913	1,665	100.0

typhoid fever in the state is unknown, but it is probable that the cases from this cause are few, certainly less than 5 per cent of the cases reported. There was not a single epidemiological case record in which the source of infection was given as flies. As a rule, it has been found that where flies can carry the infection, personal contact can also be the cause.

The manner in which the larger communities are sewered, the lack of privies, the hospitalization of typhoid cases, and the disinfection of excreta from typhoid cases, furnish little opportunity for the mechanical transmission of typhoid bacilli by flies.

Carriers as a Menace

The intermittent typhoid bacilli carrier is probably the greatest single factor in the causation of typhoid in Massachusetts today. These carriers infect but one or two cases a year, or none at all, but by personal contact or by food, particularly if they are housewives or cooks, they are responsible for many cases. In 1919 six of this type of carriers were isolated and they were responsible for only seven cases. Further investigation along this line will disclose more of these "household carriers," a most dangerous type, because of the insidious manner in which they infect their victims. There are now fifty-one carriers on record in the files of the Department, seven of whom were found in 1918 and thirteen in 1919.

The search for carriers is not an easy task and is often discouraging in results; but the careful compilation of epidemiological case records, and the securing of blood, feces, and urine from each suspected carrier for bacteriological examinations, at the lowest estimate should yield at least two carriers for every one hundred cases studied. In 1919 there were 1.4 carriers found for every one hundred typhoid cases.

Household Contact with the Sick

There were 221 cases caused by contact with a sick case; of this number, 170 cases were secondary to a typhoid case in a family. Considering the fact that there were 6,388 persons comprising the families of the 1,658 cases studied, this gives the rather startling figure that one in thirty-eight of those exposed to a case in a family was infected and had typhoid fever. This ratio is improving, for in 1918 it was 1.31, and in 1919 it was 1.41. However, if all members of the family were inoculated with "triple vaccine," this ratio would be considerably bettered, for more than one-half of the contacts had the onset of the disease three weeks or more after the physician's visit to the primary case, indicating infection from the sick person after his visit. Sixty-eight families had two or more cases, of which number three families had five cases; two families six cases; one family seven cases; and one family eight cases. These are startling figures in this enlightened era, but typhoid vaccine was not administered; if it had been, some of these secondary cases would not have occurred and lives would have been saved.

Past History of Typhoid

In 129 cases in 1918 and 1919 there had been other members ill with typhoid one year or more prior to the present case. In many instances laboratory examinations were obtained, and ten carriers were found, though it was impossible to obtain specimens of feces and urine in all cases, because of opposition from families.

In practically every case of typhoid, when a member of the patient's family gives a past history of typhoid fever, he should be suspected a carrier, and a Widal test and laboratory examinations of feces and urine should be carried out.

The Problem of Endemic Typhoid

A certain amount of typhoid fever is what may be termed "endemic,"—that is, the cases do not occur in epidemics. In 1917, 171, or 11 per cent, of the typhoid cases were in epidemics; whereas in 1919, 157, or 17 per

cent, of the cases were in epidemics. This increase in epidemic cases is the result of the reduction of endemic typhoid in the state by better sanitary conditions and the inoculation with typhoid vaccine of the men who entered the army in 1917, 1918, and 1919. It is felt that the endemic typhoid in Massachusetts is due almost wholly to the typhoid bacilli carrier.

Having located the source of infection of 26.6 per cent of the cases, it is interesting to look back fifty years and see to what causes typhoid fever was attributed. In 1871, before the typhoid bacillus was known, the State Board of Health Report gave the three possible theories of the cause of typhoid fever as follows: (1) "Propagation by drinking water made foul by the decomposition of any organic matter, whether animal or vegetable, and especially by the presence in such water of excrementitious matters discharged from the bodies of those suffering from typhoid fever. (2) Propagation by air contaminated by any form of filth, and especially by privies, cesspools, pig sties, manure heaps, rotten vegetables in cellars, and leaky or obstructed drains. (3) Emanations from the earth occurring especially in the autumnal months and in seasons of drouth."

Confirmation by Widal Test

The results of the Widal test were given for 1,125 cases in 1918 and 1919. There were 1,039 positive and 86 negative results. Undoubtedly, more of the cases had the test done, and most of the 86 negative tests later proved to be positive after the epidemiological blank has been forwarded. Considering these figures alone, 92 per cent of the cases investigated had a positive Widal test, confirming the clinical diagnosis. The majority of cases in which the Widal test was lacking were in urban communities.

The number of cases on which a study of the age and sex could be based is greater than for other topics of discussion, for these data are given on the postal card reporting the case of typhoid fever. For comparative purposes the cases for the past three years are considered and there were 3,059 of 3,552 cases on which this information is available for 1917 to 1919 (Table III).

Age and Sex Groups

The striking effect produced by the immunization of men of the draft age in the army, that is in the 20-24 and 25-29 year groups, is clearly seen by comparing the 1917 figures with 1918 or 1919. In 1917 the largest number of cases occurred between the ages of 20-29, whereas in 1918 and 1919 the greatest age incidence was in the group from 10-19 years. Only seventeen persons were reported as having typhoid who had been given typhoid vaccine from one to four years previous to the onset of the disease. Considering the fact that in many cases the immunity conferred by inoculation is good for but one year, this is a very good showing.

The distribution of 3,534 cases in 1917, 1918, and 1919 between the sexes showed that males predominate markedly. In eighteen cases the sex was not given (Table IV).

The greater incidence of cases in the male group is apparently due to the greater opportunity offered for infection by the type and manner of occupation and carelessness in eating meals. In the younger age groups, the places and manner in which boys seek recreation, as in woods, swimming, and dumps, undoubtedly are a factor in the greater incidence of the male group.

In 1,308 cases the occupation was given, but the information is of little value except as it showed the great number of school children who had the disease, which would indicate that parents who have a history of typhoid fever should be considered as suspected carriers and should be investigated (Table V).

It is to be regretted that twenty-six nurses had typhoid during the two years and that only one had been inoculated with typhoid vaccine. It brings typhoid vaccine again to the front, for, if nurses were inoculated yearly, there would probably be no nurses ill with typhoid. Two nurses were proved to be carriers, one infecting a patient, and the other six persons through the agency of milk.

The nationality of the cases was furnished in 1,515 cases, distributed as shown in Table VI.

Fatality Rate Significant

The ratio of deaths reported in 1919 to cases reported was the lowest for several years, for only one died to each 9.1 cases reported, and the fatality rate is correspondingly low, as appears in Tables VII and VIII.

The high fatality rate of 1918 was apparently due to a certain number of typhoid cases being reported as influenza, rather than an increase in the virulence of the typhoid bacillus; for the high fatality rate existed during the months the influenza epidemic raged. Incidentally, the 1919 fatality rate is the lowest in the history of the disease in the state.

There were fewer cases reported in 1919 than any other year, establishing the record morbidity rate of 23.7 per one hundred thousand for Massachusetts. The seasonal distribution of these cases is set forth in Table IX.

As in previous years, more cases occurred in the late summer months. The total cases from August to October were 434, or 46 per cent of the total cases reported in 1918. The monthly distribution of cases based on the percentage of the total cases reported is shown in Table X.

The striking facts shown in this table are the small number of cases reported during October in 1918 as compared with other years, and the larger number of cases reported in July than in previous years. The small number of cases reported in October and November is due in part to the influenza epidemic, during which cases of typhoid were diagnosed as influenza because of the similarity of symptoms.

In 1919 the monthly incidence was the same as 1917 and earlier years, with the exception of January, February, and March, during which months an epidemic of thirty-eight cases occurred, due to water, which produced the slightly higher percentages for these months.

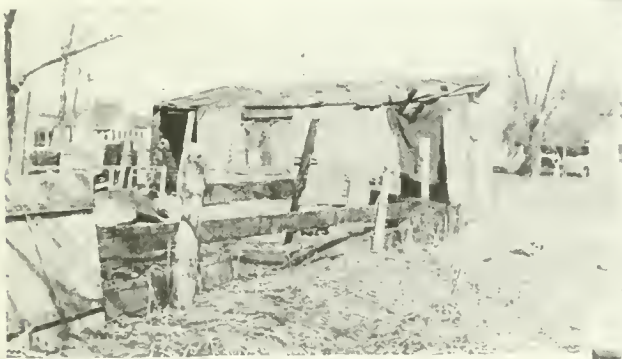
PUBLIC HEALTH WORK FOR RURAL DISTRICTS

By E. MARSH WILLIAMS, M.D., Director, Board of Health, Oskaloosa, Iowa

THE task of organizing a health district and planning work first along those lines in which a community seems measure by the character of the problems presented and

A condemned, typhoid contaminated well. The house is closed, all the family being in the county hospital with typhoid fever.

the funds available within the respective district or municipality; for example, that district located within an entirely agricultural part of the state, away from large cities and with many small towns, would have



Such structures as these are ordered out. Pig sheds and pens have no place in town.

very different problems from the district about a larger city or a manufacturing, shipping, or mining community. However, a general program can be outlined and modified to meet the various conditions presented.

It is necessary to use common sense and tact and work first along those lines in which a community seems to be most interested. Then the program may be extended as the campaign of education is carried on in accord with the outlined program:

In most districts and municipalities, the public school system offers the best field in which to begin the work. Later, the subject of sanitation, or both may be worked together. If it is decided to inaugurate an intensive campaign in some locality for three or six months, the following outline could be made:

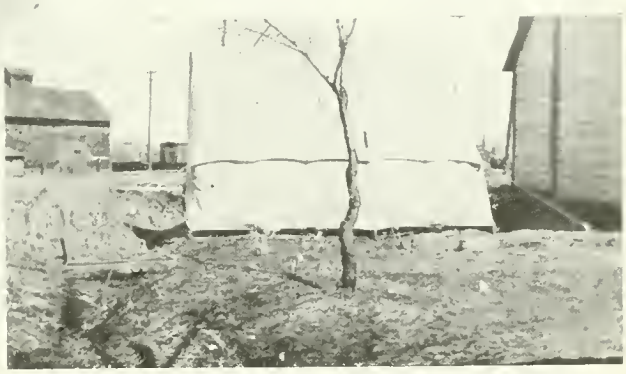
(1) Educational work, consisting of health talks, demonstrations, motion pictures, distribution of literature, home visitation, and organization of health centers.

(2) Water and soil pollution work, consisting of removal of condemned privies and cess pools or connection to drainage systems; the analysis of drinking waters and the study of drainage areas; the protection of water supplies and milk and dairy products; and the

The solution of a difficult problem. The reservoir of the water works plant of Oskaloosa, Ia., situated at the lower end of a ravine which drains a barnyard and pig pen three hundred yards to the left. In the lower left hand corner is a pig wallow which drains into the reservoir.

relations of polluted waters to water borne diseases.

(3) Vaccination and distribution of free vaccine, serum, and antitoxins.



The way Mohaska County, Ia., is taking care of her white plague patients.

Three bright prospects for the Nutrition Class. All under weight, and all gaining steadily under the right régime.

(4) The medical inspection of schools with follow-up to get the results of the inspection.

(5) An effort to coordinate all the public health agencies available in the community.

Such a program could not be undertaken until the organization of the working unit and the establishment or rental of a suitable laboratory is provided. If there is a laboratory in the district, either municipal or private, the cheaper way would be to arrange, if possible, to utilize it, at least for a time. However, with an outlay of from three hundred to five hundred dollars a serviceable laboratory can be installed.

As to securing a technician, the inspector or clerk could be taught to do much of the work, leaving the matter of diagnosis to the health officer. Such work as urinalyses, blood counts, gastric analyses, occult blood tests, and other simple analyses could be done for physicians and hospitals and thus stimulate an interest in the medical society for public health matters. A fee could be charged for the work for the upkeep of the laboratory. This would not necessarily interfere with the proper functions of the laboratory for public health work.

Constructive Work in Rural District

In outlining a program of constructive public health work in a rural district when little or nothing has been done, three principal points are to be considered: (1) The organization of the working unit; (2) the organization of all the available health agencies, and (3) the organization of the work as a program.

In the first step, there is a wide range of limits, depending upon the available funds for public health work. A liberal working unit in a district of twenty-five to thirty thousand inhabitants should include a health commissioner, three public health nurses, one of whom might be a general nurse, one a tuberculosis nurse, and one a school nurse, one clerk, and one laboratory technician. In the towns within the health districts it would be necessary to have a deputy health officer with perhaps a general nurse.

In considering the second step a real problem presents itself; for the health officer must not be too aggressive in his zeal for public health achievements, but with patience and tact and perseverance, must try to coordinate all the local health activities and bring them to a state of organization where they may be a part of the program of the working forces having a unified program of activities and team work. It would probably be advantageous to have a representative advisory council formed, to consist of one member chosen from each of the following organizations: the Red Cross, woman's club, commercial club, ministerial association, medical society, the Child Welfare Association, Child Labor Committee, the Board of Education and others. This Council, together with the nurses and health officer, should meet regularly to plan and arrange the activities of the sub-department of public health nursing in all its branches, because it is here that contact with the individual, with the family, and with the life of the community is made. The confidence and the cooperation of the people, together with the education of the public in health matters, is made possible through the activities of these available health organizations.

The hour for milk is enjoyed by this nutrition class more than recess.

In the consideration of the third step, begin with the real activities of public health. Just where to begin or what problem to attack is variable with conditions in different districts and municipalities. In general the best starting point is in the public school system, beginning with the inspection and health supervision of the school children, recording and using a follow-up system in all defective cases. The establishment of dental and medical clinics should be undertaken as the demand may warrant. Through the school work, the nurses work out into the homes and thus build up a field of tuberculosis work which can be followed up during the summer months, together with child welfare work. Health lectures and demonstrations should be given in the schools and the Parent-Teachers' Associations. There should be the establishment of warm school lunches, especially in rural schools, stimulation of Health Crusade work, sanitation, distribution of literature, free vaccination and antitoxins to the poor, and the study and control of communicable diseases.

The next division is the working program in sanitation. This field covers a multitude of sins and omissions. Here are two lines of work, one to remove hindrances to public

health, the other to replace with modern structures and methods,—things which will protect and aid the public health. These efforts should be directed along the lines of carrying out a definite intensive campaign in the rural towns and districts towards securing a safe water supply; the cleanly disposal of human excreta, barnyard drainage; the protection and care of milk supplies and products; the bedside control of communicable diseases; the elimination of cesspools and unsanitary privies, especially in the towns; the extension of the sewerage or water carrying system wherever possible; the installation of sanitary privies in rural districts; health education along the lines of prevention of water borne diseases or typhoid fever; the elimination of flies and other insects, and protection against them; an educational propaganda along sanitary lines and a familiarity with the rules and regulations of the State Board of Health and municipal ordinances.

In the rural towns, it is essential that the food supplies be guarded and all places where food and drinks are handled should be kept clean and protected from dirt and flies.

The laboratory should be utilized in the analysis of waters, foods, milk, and in any other way necessary to render aid in the diagnosis and prevention of communicable diseases.

After the first few months or year of getting organized and started, the second year should show the beginning of actual work. Then can be taken up surveys in various lines, *viz.:* water survey, sanitary survey, tuberculosis survey, child welfare survey, and such activities. From these plans further work may be formulated.

Outline or Program of Public Health for District or County Work

I.—Organization of working forces.
- A.—District or County Health Commissioner.
- B.—Public health nurses.
- C.—Inspector.
- D.—Clerk.
- E.—Municipal deputy health officers.
- F.—Advisory councils.
- G.—Local boards of health.
- H.—Establishment of public health laboratory.

II.—Coordination of all available Health Agencies.
- A.—City councils.
- B.—County commissioners.
- C.—Women's clubs.
- D.—Board of education.
- E.—Commercial clubs.
- F.—Medical societies.
- G.—Social service leagues.
- H.—Child welfare associations.
- I. —Red Cross.
- J. —Health crusaders.
- K.—Ministerial associations.
- L.—Home service leagues.

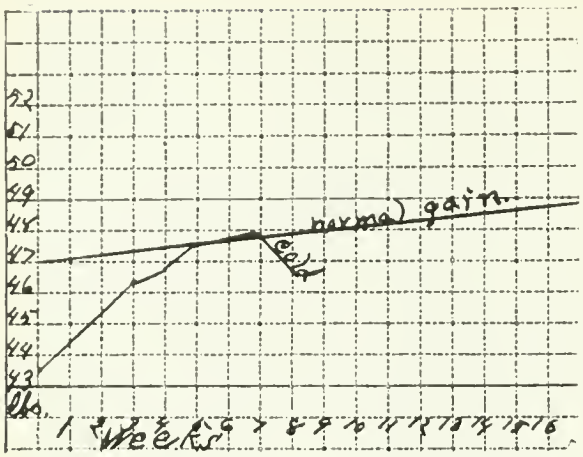
III.—Constructive Activities in Public Health.
- A.—Child Hygiene.
  1.—Inspection and health regulation of children's institutions.
  2.—Inspection and health regulation of charitable institutions.
  3.—Correction of physical defects.
  4.—Periodic inspection of schools.

"In with the New." Installing a new toilet. Some of the forces at work during clean-up week.

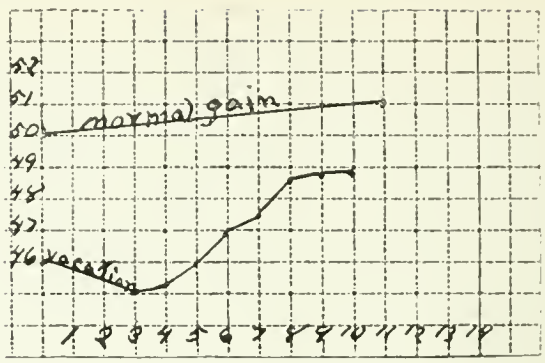
A well equipped County Public Health Laboratory.

The Park as it appeared after clean up week in Oskaloosa, Ia.

"Out with the Old" A type of toilet that must go.



The chart of Mary W., age 7 years, height 45 inches, weight 43.5 pounds.



The chart of Pauline S., age 7 years, weight 45 pounds, shows the marked and constant improvement achieved in nutritional work at Oskaloosa, Ia.

5.—Recording and classification of defects.
6.—Follow up work for defective cases.
7.—Treatment for (a) vision, (b) hearing, (c) nose and throat defects, (d) deformities, (e) skin, or (f) teeth.
8.—Vaccination.
9.—Isolation of infectious cases.
10.—Examination of nervous and mental cases.
11.—Special tubercular work.
12.—School lunches: (a) private and public support.
13.—Home instruction by: (a) health officers, (b) school nurses, (c) physicians, (d) school teachers, and (e) literature.
14.—Physical training by special instructors in: (a) athletics, and (b) gymnastics.
15.—School sanitation, including: (a) ventilation, (b) cleaning, (c) fumigating, (d) heat, (e) light, (f) toilets and sanitary privies, (g) drinking water, (h) suitable desks and seats, and (i) educational literature.

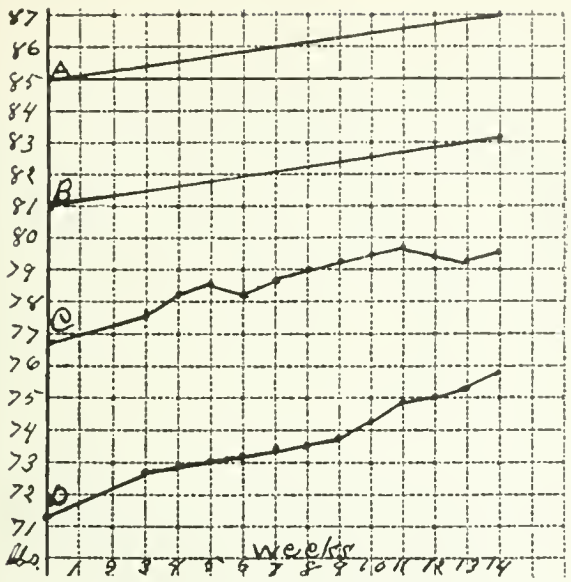
B.—Child labor.
1.—State regulation. (a) age, (b) hours, and (c) physical examinations.

C.—Communicable diseases.
1.—State and local regulations: (a) isolation, (b) quarantine, (c) release, (d) fumigation, and (e) vaccines and antitoxins.
2.—Tuberculosis survey: (a) laboratory work for dispensary for diagnosis and treatment, (b) follow-up work, (c) sanitation, (d) home treatment and supervision, (e) open air schools, and (f) food and rest.

D. General health measures.
1.—Water supplies, including: (a) surveys, (b) protection against pollution, (c) laboratory analysis, (d) municipal supplies, (e) wells and cisterns, (f) methods of purification, (g) regulation of public drinking places, (h) regulation of public baths and pools, (i) educational propaganda, (j) proper drainage and protection of water sources, and (k) study of water-borne diseases.
2.—Milk and milk products, including: (a) state regulations, (b) inspections, (c) laboratory examinations, (d) pasteurization, (e) refrigeration, (f) grading, (g) cattle testing, (h) sanitary handling, and (i) city ordinances.
3.—Foods: (a) state regulations, (b) supervision of: (1) slaughter houses, (2) factories, (3) bakeries, (4) markets, (5) restaurants, (6) produce houses and stores, (7) examination of food handlers, and (8) city ordinances.
4.—Sewerage and sanitation, including: (a) state regulations, (b) surveys, (c) proper sewerage disposal, (d) elimination of cess pools and privies in towns, (e) installation of sanitary privies in rural districts, (f) protection of public water ways, (g) minimum standards of pollution of water supplies, (h) purification methods, (i) rural sewage disposal, (j) municipal sewerage disposal, (k) relation of sewage disposal to disease, and (l) intensive campaign in municipalities and rural districts to secure: (1) safe water supply, (2) cleanly disposal of human excreta, (3) safe milk, (4) control of communicable diseases, (5) garbage disposal, (6) fly and insect control, (7) clean-up periods, and (8) improved methods of sanitation.
5.—Public health education to cover: (a) campaign of education, (b) schools of health, (c) schools of domestic science, (d) teachers of hygiene, (e) health centers, (f) lectures, (g) books, (h) magazines, (i) newspapers, (j) posters, (k) tracts, (l) leaflets, (m) motion pictures, and (n) demonstrations at public gatherings and social clubs.
6.—Rules and regulations: (a) national laws, (b) state rules and regulations, (c) municipal ordinances.

The first year's work would largely be taken up in the organization as outlined in Part I, and a beginning on Part II with some work in Part III.

The second year's work would cover parts of Section III and the third year's work would carry out in more



Group chart of Nutrition Class of eighty-six members. A—Graph of average normal weight and the gain of those who do not receive milk from the school. C—Graph of actual average weight and gain of those who do not receive milk from the school. B—Graph of average actual weight and gain of those who receive milk twice daily at school. D—Graph of average actual weight and gain of those who receive milk twice daily at school. Gain on an average for each child about three pounds, while those who did not receive milk at school gained only about one-half pounds on an average.

detail the work outlined in Part III. An estimate is given of the costs for the first year in a health district comprising twenty to thirty thousand inhabitants.

Liberal Budget Allowance

I.	Health Commissioner	$ 4,000
II.	Public Health Nurse	1,800
III.	School Nurse	1,500
IV.	Tuberculosis Nurse	1,800
V.	Inspector	1,200
VI.	Clerk	1,000
VII.	Laboratory Installation	500
	(a) Laboratory supplies	100
VIII.	Automobile	600
	(a) Car upkeep	100
IX.	Office Supplies	200
X.	Clinics	100
XI.	Hospitalization	200
XII.	Venereal Work	200
XIII.	Incidentals	100
		$13,400

Conservative Estimate

I.	Health Commissioner	$ 4,000
II.	Public Health Nurse	1,800
III.	Inspector	1,000
IV.	Clerk	1,000
V.	Laboratory and Installation	400
VI.	Automobile	600
	(a) Car upkeep	50
VII.	Office Supplies	200
VIII.	Venereal Work	100
		$ 9,150

In the organiztaion of a rural health campaign on this basis it is a part of the plan to secure from local health agencies and private sources funds for: (1) clinics, (2) food and supplies for sick, (3) hospitalization, and (4) tuberculosis work.

PREVENTING ANTHRAX

The Board of Health of New York has put into effect regulations requiring the sterilization of hair used in toilet articles, as a means of preventing anthrax. The regulation reads: "No person shall use in the manufacture of brushes or cloth, any animal hair which has not been sterilized by a process prescribed or approved by the Board of Health, nor shall any person bring into, or offer for sale, sell, or deliver in the City of New York, any brush or cloth containing animal hair unless the same shall have been sterilized.

"It shall be the duty of manufacturers of shaving brushes, tooth brushes, hair brushes, nail brushes, or other toilet brushes intended for human use, to cause his name or trade-mark, the place of manufacture, and the word 'sterilized' to be permanently, clearly and legibly painted or branded upon every such brush before offering for sale, selling or delivering the same in the City of New York."

INTERNATIONAL PUBLIC HEALTH

The opportune moment of the first meeting of the Medical Advisory Board of the League of Red Cross Societies has been utilized for the appearance of the first number of the *International Journal of Public Health.* This journal will be published bi-monthly by the League in four editions, English, French, Italian, and Spanish. Dr. Thomas R. Brown is the editor, with a staff of one associate and six assisting editors under him. The first three numbers are to be issued *gratis* in all parts of the world, but with the four issues in January, 1921, a subscription rate of $5 per year will be instituted.

The first issue contains as its leading original article an essay by Prof. A. Calmette on the protection of mankind against tuberculosis; part of a report by Dr. Richard P. Strong on the antityphus campaign in its bearing on Poland, and a statement by Dr. George C. Whipple on the world sanitation in the twentieth century.

COMPENSATION OF HEALTH OFFICERS

If health officers are to be adequately rewarded for the duties and responsibilities resting upon them, the education of the public with regard to the meaning of thorough public health work must be accelerated, according to Dr. John A. Ferrell of the International Health Board, Rockefeller Foundation, New York City.

In a survey reported in the July issue of the *American Journal of Public Health,* in State health work the compensation scale for the chief executive officers of health for the year 1919 ranged from $1,000 in Arizona to $10,000 in Pennsylvania. In the United States Public Health Service compensation of commissioned officers has recently been advanced from 15 to 30 per cent. In city health work, likewise, schedules have increased and numerous vacancies are announced in city health work and among private health agencies at salaries ranging from $2,500 to $7,500 per year. Although the compensation schedule for health officers has been too low, it has been steadily increasing year by year for the past ten years. The present shortage of qualified men indicates that the compensation schedule will continue to advance.

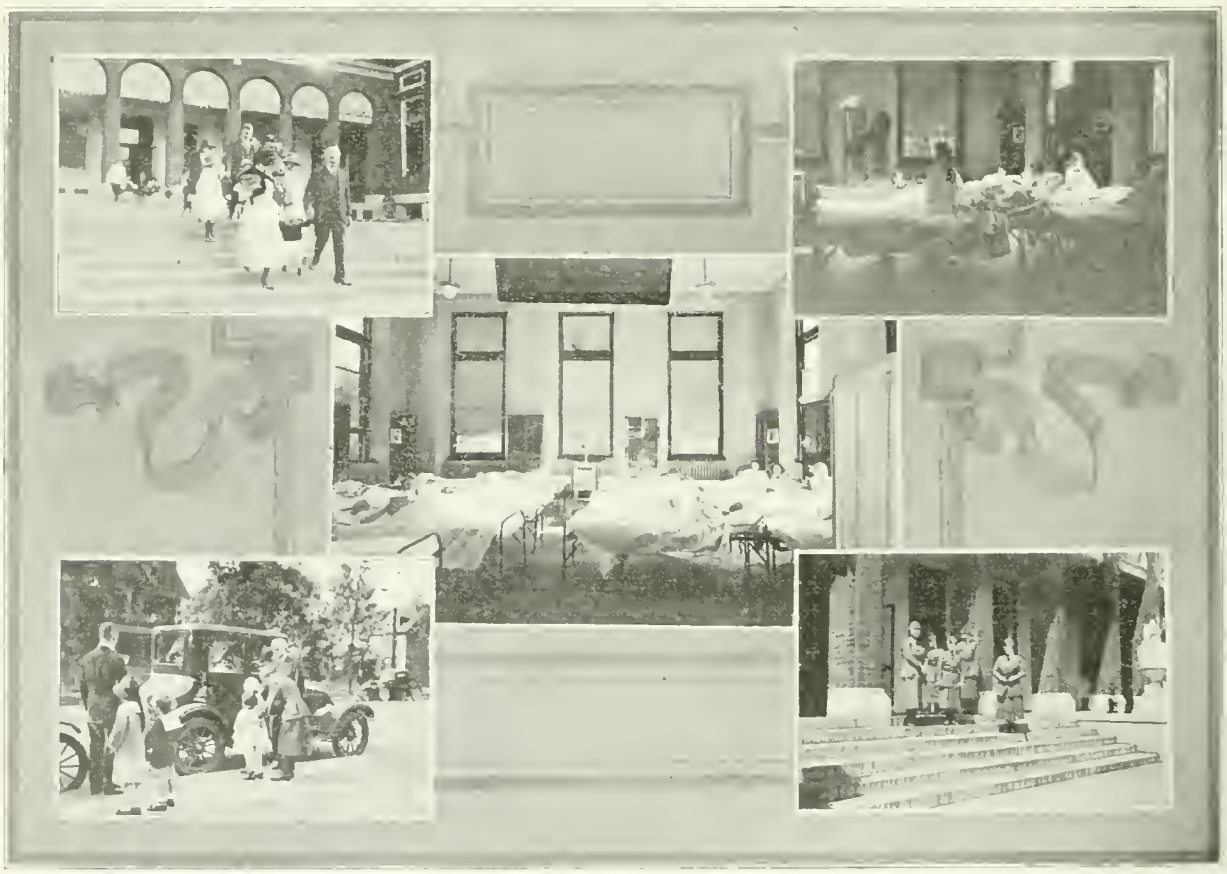
The associations of health officers should give direction to the movement, which has already gained tremendous momentum, by keeping the public informed regarding achievements in the prevention and control of disease, by interesting in special training those medical students, medical interns, and other persons who can be used in the work, and by giving guidance and support to institutions which are offering creditable courses in public health.

A TONSIL CLINIC AT ROCHESTER, N. Y.

THE Rochester Dental Dispensary opened an emergency clinic on July 26, 1920, for the removal of diseased tonsils and adenoids among the children of Rochester and Monroe counties, New York. This clinic was decided upon at the instance of Mr. George Eastman, who founded the dispensary some years ago. The dispensary was especially arranged for the handling of forty cases a day. Emergency rooms were equipped and special provision was made for the entertainment and care of the children. The cooperation of the city Department of Health, of the American Red Cross, and the various hospitals of the city made the campaign effective throughout the city and county. The children were transported to and from the dispensary by the Red Cross Ambulance Corps, who volunteered for the service.

The children were brought to the dispensary on the afternoon of the day before the operation. They received a physical examination and were entertained with motion pictures and music during the evening. In the morning the operations were performed and the children were transferred to the hospital wing specially fitted up for their reception, where they were kept until the following day. The receiving wards were far removed from the hospital wards, an arrangement which kept the incoming children from contact with any of the patients who had been operated. The dispensary made a charge of five dollars for the operation and for the care of the children, but even this small fee was remitted in the cases of children whose parents could not pay.

The surgical part of the work was performed by Drs. Edwin S. Ingersoll, Harry W. Edwards, Warren Woden, Ralph Honiss, Robert L. Iverson, and Leonard W. Jones. The house physicians were Drs. Walter D. Edwards and Richard A. Leonardo. The nursing service was directed by Mrs. Eleanor Spencer, head nurse at the dispensary.



Upper—Dr. Harvey J. Burkhart, director of Rochester Dental Dispensary, accompanying children to awaiting automobile when they leave for their homes.

Lower—Dr. Harvey J. Burkhart bidding farewell to tonsil and adenoid patients departing from the Dental Dispensary. The children are about to enter an automobile of the Motor Corps.

Center—Ward scene in Rochester Dental Dispensary, during the progress of the tonsil clinic

Upper—Ward scene at Rochester Dental Dispensary where the tonsil clinic is in progress. The little patients have been bathed and fed and now await the arrival of "Hospital Happiness" motion pictures.

Lower—Members of Woman's Motor Corps, Rochester Chapter, American Red Cross, who are transporting children to and from the tonsil clinic at the Rochester Dental Dispensary.

The Rochester Dental Dispensary has been under the charge of Dr. H. J. Burkhardt from its beginning. It has developed during the last year a clinic for the removal of diseased tonsils and adenoids and during the year on this service performed about twenty-five operations per week. The special clinic was deemed necessary to improve the situation. It is expected that fully fifteen hundred children will be operated upon during the clinic. Subsequent health work among these children will be noted with interest as no other city, so far as reported, has attempted so comprehensive a service of this kind.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

NATIONAL NURSING HEADQUARTERS ESTABLISHED

DELEGATES at the Atlanta Convention voted in favor of establishing headquarters for the three national nursing organizations—the American Nurses' Association, the League for Nursing Education, and the National Organization for Public Health Nursing. The necessity for such joint headquarters being established immediately was urged because of the need of a center for the recruiting campaign which the three organizations have undertaken, assisted by the American Red Cross.

Two offices have been leased at 156 Fifth Avenue, New York City, where the National Organization for Public Health Nursing is located, and it is probable that within the year branch offices will be opened, one in Chicago and one in the far West.

The notable and rapid development of the N. O. P. H. N. sets an encouraging precedent. In 1912 this organization was first established in an office with an executive secretary, Miss Ella Phillips Crandall, and now extends over the entire country, with branch offices in Cleveland and Chicago, and branch offices are planned for the far West and South. The personnel of its staff includes eleven full time nurse secretaries.

If organizations evolve in accordance with demand, a wonderful future for the joint Nursing Headquarters is assured. The Nursing Committee on Arrangements is composed of Miss Clara Noyes, president, American Nurses' Association; Miss Sara Parsons, Miss Mary Gardner, and Miss Anna Goodrich. Among the activities proposed are: a national recruiting campaign, a campaign to improve nursing education, and a central occupational clearing house for nursing credentials.

There is little doubt but that a recruiting campaign is badly needed. There is much doubt about the best methods of conducting such a campaign. Several methods have already been tried out, and it is with the greatest interest that we await the adoption by the National Recruiting Committee of a method of procedure.

Under the auspices of the Council of Defense a nation-wide recruiting effort was made during the war, as a result of which many more than the usual number of young women with high school and college education entered the schools for nurses. It is unfortunate that comparatively few of these recruits continued their training after the Armistice took away the thrill of possible war adventure.

The most unfortunate part of that campaign, however, was the fact that young women inquiring about nursing were referred to any or all accredited schools and, even though told what constitutes a good school, hundreds of them spent a few months in schools where living conditions were unbearable, where hours of duty were too long, and where they paid in drudgery a higher tuition fee than is paid by any other class of students anywhere. The result has been that in almost every school, club, or college where we now go to talk on "Nursing as a Profession," at least one young woman is present who enters wholeheartedly in the discussion, giving such true, vivid, and detrimental arguments against nursing as a profession, from her own or a near friend's actual experience, that the speaker finds little satisfaction in arguing that they were informed what constituted a good school.

Our lessons from campaigns of this kind should be that palliative relief for shortage in schools for nurses is possible, but is *pro tempore*, and the advantages are always greatly discounted by the harmful protestations from a dissatisfied public, if applicants are not more explicitly warned against the poor though sometimes accredited school.

We have learned another lesson concerning methods of preparing publicity. The Central Council for Nursing Education, with headquarters in Chicago, has been conducting a successful recruiting campaign for a group of very good schools for nurses in the central West. They are finding that because all of their publicity material is carefully prepared, printed on good paper, and put out in expensive, first class form, the recruits applying to the schools are of exceptionally good caliber.

Watch any magazine stand for a few hours and note the difference in the type of people which are attracted by and carry away the cheap, gaudily covered magazine as compared to those who select plain, but more dignified looking pamphlets. Dancing manikins may sell chewing gum, but there is nothing dignified in chewing gum.

All literature which is distributed about nursing should be prepared with the same regard for reputableness that usually characterizes announcements from educational institutions of a high order, and of the very select and distinctive commercial houses of recognized worth.

Cheaply prepared nursing leaflets can be thrown around; they are hard to give away, but costly. Literature, if carefully prepared, is not wasted. It is always kept, read, and passed on. Results are tripled in numbers and quality. One does not have to give it away, as the literature that is worth while may be sold at cost or even at a profit. From recent experience with the large sale of literature originally intended for free distribution by the Central Council for Nursing Education, the editor believes that the proper kind of nursing bul-

letins, posters, cards, blotters, or calendars can be printed and offered for sale by the National Nurses Recruiting Committee at a margin which would meet all expenses for the nation-wide campaign. A further advantage would be that literature could be sold to and used by only those schools coming up to a given educational standard.

The wholesale distribution of nursing literature, lectures, and information concerning all schools for nurses by the Joint Nursing Committee at this time would be synonymous with the ignorant hurried man who puts a thin coat of cheap varnish on the old rough painted table top without first smoothing down and improving the foundation.

A serious shortage of student nurses exists in almost every school for nurses. Hospital boards everywhere are eager to do what anyone tells them to do, in order to care for their patients and avoid cutting down the hospital income by having to close wards and floors because of lack of student nurses. If the three national nursing organizations which have so long fought for higher educational standards for nurses would come out strongly now for central schools and association of schools for nurses with educational institutions which would assume direct responsibility for the teaching, and if the joint organizations would recruit for only these schools, helping all desirable schools to secure proper affiliation, there would be a tremendous awakening on the part of hospital boards all over the country as to the futility of running hospitals wholly or in main by means of pupil nurses and giving them in return as little education as possible.

The increasing popularity of hospitals, the demand by the public for nurses trained far beyond the bedside nursing stage, the better remuneration and improved working conditions in other occupations, will soon make it obligatory that hospitals employ many more attendants or graduates, thereby becoming either training centers for bedside attendants or well conducted laboratories for the nurses in training.

We are thrilled by the possibility of what the concerted action of the three national nursing organizations, strongly backed by the American Red Cross, can do now, when opportunity knocks as it has never knocked before, when the time is ripe for a radical change from the present economically unsound system for both hospital and student, to a fundamentally sound and practical basis of education which will provide nurses for the world and prepare nurses for their unprecedented responsibilities.

It can be done now, but next year may be too late.

ORGANIZATION OF AN INDUSTRIAL NURSES' CLUB

By MRS. CARRIE B. CORRELL, Personnel Supervisor, The Cleveland Telephone Company, Cleveland, O.

IN attempting to organize any association, it is first essential to locate several people of similar interests who have constructive ideas. This small group of willing workers will form a nucleus around which can be builded an active organization.

Cleveland nurses engaged in industrial work were conscious of their need for exchange of ideas prior to the convention of the National Association which was held in Cleveland in May, 1918. Those who attended the various sessions of the Convention were stimulated to immediate action, and it is due to the incentive received at that time and to the untiring efforts of those most interested that the Industrial Nurses' Club of Cleveland is now in existence.

The Situation Surveyed

The week following the convention a group of eight nurses met to devise ways and means of reaching all graduate registered nurses engaged in industrial work, as a result of which conference a committee was appointed to make a survey of the city. Through the Red Cross Nursing Center, the Alumni Association, and telephone inquiry of large industries as to whether a nurse was employed by their organization effort was made by this committee to get in touch with all industrial nurses.

When a member of this Committee succeeded in reaching the nurse personally, she announced her own name and business connection then gave the information that a committee had been appointed to locate all graduate registered nurses who were engaged in industrial work. If she were one of this number, they stated their wish to extend to her an invitation to meet with them at an appointed time, the formal invitation being sent by mail, announcing the date and purpose of this meeting.

If she replied that she was a graduate nurse but not registered, the advantages of registration were presented to her, and an appeal made that she seriously consider taking the State Examination.

More than fifty nurses received invitations to attend this meeting, but only thirteen responded. However, we did not measure success in numerals, but by the manifestation of enthusiasm on the part of those present.

A chairman and committee were appointed to call a meeting in September, 1918, for the purpose of electing officers, outlining constitution and by-laws, deciding upon a suitable name for the club, the qualifications for membership, and dues.

This meeting was held September 10, 1918. Only those who were known to be Registered Nurses received an invitation to this meeting. The invitations were again given by telephone, effort being made in this way to convey a personal appeal. Thirty nurses responded. The members of this group are recorded as charter members. The object of this meeting was successfully carried out and the industrial Nurses' Club of Cleveland came in existence.

Two members assumed the responsibility of advancing sufficient funds to cover postage. Stationary and mimeographed invitations were donated by the firm where these nurses were employed. Application blanks were prepared by a firm employing another member. Three hundred copies of the constitution and by-laws were printed in booklet form, at a reduced rate, through the efforts of another member who is employed by a firm interested in printing.

The Dues Are Nominal

The small sum of one dollar initiation fee and one dollar yearly dues have been adequate to cover current expenses. It has not been necessary to rent an assembly hall, as we have been exceedingly fortunate in having the privilege of using an employees' rest room in a business house centrally located and very accessible. The most important details of organization can be briefly outlined.

The Aims of the Club

The aims of the club are best explained in Article II of the Constitution which reads as follows:

The object and purposes of this organization shall be:

Section 1. To discuss problems relating to the health and well being of workers in industry which come within the province of a nurse.

Section 2. To stimulate through the work of the Club, not only the enthusiasm of its members but the interest of the general public and especially of employers, to a fuller understanding of the value of the nurse's work in industry.

Section 3. To develop through discussion an efficient and practical standard for the nurse in industry, including the personal and professional qualifications of the nurse.

The result of adopting this article has been most gratifying. The discussion of industrial problems and nursing standards have been very beneficial. It is the aim of the Club to assist in every possible manner to maintain the very highest nursing standards. We have had frequent and intense discussion on the subject of State Registration as one of our requirements for membership. We still feel that the standards as required for State Registration are none too high and our Membership Committee continue to request each applicant to present her certificate to a member of this Committee before her name is proposed for membership.

Club Makes Annual Report

The Annual Report of the Club as presented to its members at the annual meeting which was held in January, 1920, makes this statement as to the Club's benefit to nurses.

It is with considerable satisfaction that I give to you the report of the Club's activities and progress for the year 1919.

From a membership of thirty charter members at its organization in September, 1918, we now register a membership of fifty-two. A recent survey of the city shows there are eighty-six (86) nurses engaged in industry in Cleveland.

In presenting the activities of the Club for purposes of record, the three months of 1918 are included in this report.

With the exception of August, 1919, monthly meetings have been held regularly on the second Tuesday of each month. The first monthly meeting was held in September, 1918. Officers were elected and general outlines of the constitution and by-laws were discussed. The present attractive Constitution and By-Laws are the result.

The detail of organization naturally consumed a great deal of time but has not excluded the fundamental motive for its existence, which may be generally stated as educational in purpose.

The following list of topics and speakers has been presented at the fifteen meetings to date:

Importance of the Nurse's Work in Industry—Dr. A. F. Voak, of the National Acme Company.

Industrial Work and State Compensation—Mr. Wilson and Mr. Maloney, of the State Industrial Commission.

Lakeside Unit in France—Miss Allison, Former Chief Nurse of Base Hospital No. 4.

Home Economics and Family Budgeting—Mrs. Lapp and Mr. Lincoln, Society for Savings Bank.

Outline of Public Health Course—Miss Evans, instructor, School of Applied Social Science, Western Reserve University.

Red Cross Community Teaching—Miss Hanson, director of Red Cross Teaching Center.

Industrial Dietetics—Miss Ramsburg, graduate dietitian, Royal Baking Powder Company.

Industrial Health and Means of Combatting Influenza—Dr. H. L. Rockwood, City Commissioner of Health.

The Opportunities of Physician and Nurse in Industry—Dr. Davis, Standard Parts Company.

The program for the remainder of the meetings was in the form of round table talks presided over by a club member. Topics of general interest have been discussed with benefit and satisfaction to those present.

Twenty-seven club members responded to the cordial invitation of the employment managers group of the Cleveland Chamber of Commerce to attend a banquet at the Chamber of Commerce. Mrs. Alice Gitchell Kirk addressed the meeting on industrial dietetics.

The July meeting was held in the form of a picnic at Edgewater Park. The September meeting as a banquet at Shore Acres Club.

An interesting feature of the Club's work was the letter sent to more than a hundred general managers of Cleveland's large industries informing them of the existence of the Club and its objects. Many responses of interest and approval were received.

Several reports of adverse criticism were received during the year which, of course, means a certain form of interest and invariably an invitation to investigate the object of the Club. As a group of intelligent business women, we can safely adopt the motto that "Every knock is a boost," and cheerfully accept criticism.

The Woman's Industrial Club, affiliated with the Young Women's Christian Association, had extended an urgent invitation that we use their club rooms, and this invitation was accepted for two meetings, but for various reasons this arrangement was unsatisfactory and, through the courtesy of the Cleveland Telephone Company, meetings have been held in one of the class rooms of their training school.

We are now about to make another step forward. The Committee on New Nursing Center of Cleveland have included the Industrial Nurses Club in the group of progressive nursing activities, and have asked that we hereafter be affiliated with the New Center and hold our meetings at that place. They, in their outline, propose that two members of this Club be on the Advisory Council of the New Nursing Center.

The report, as given, represents untiring effort on the part of those who have served on committees and we owe them a debt of appreciation, more especially because of the fact that all members of this Club are occupying positions of large responsibilities, and their hours of leisure are few. It is, therefore, a foregone conclusion that this Club is now in existence because of their efforts, which were given cheerfully and at a personal sacrifice.

Since this report was submitted, we have had the pleasure of hearing Mrs. Anna Staebler address the Club on the work of the New England Industrial Nurses Club.

Mr. Lintz of the National Safety Council gave an address on "Accident Prevention," and Dr. Ward of the Parke Davis Company gave an interesting stereopticon lecture on preparation and use of vaccine and serum.

Talks Have Educational Value

The program of interesting subjects provided for the various meetings are self-explanatory as to their educational value. The round table talks have been most valuable in the opportunity offered for the exchange of ideas and ideals. They have been an inspiration for advancement in the industrial field as well as to promote general nursing interests and standards. Many members have expressed their regret that more of the meetings have not been given to round table work, but this has not been

possible, as the Program Committee has found it difficult to accommodate speakers who have requested the privilege of addressing the Association.

As a Club and as individuals, we fully appreciate the benefits we have derived from closer association made possible through organization. We also believe that any organ which is beneficial to a special branch of nursing must also be of value to the profession as a whole.

The Club's Benefit to Employers

One of the big problems of the business world today is how to devise ways and means of increasing production and efficiency. We who are in daily contact with business activities fully appreciate that production is only possible through increasing the efficiency of the individual employee. We also know that efficiency depends largely upon their mental and physical well being, vastly more so than upon their natural ability.

As a result of this realization employers of large numbers of people have introduced the trained nurse into their industries. Primarily, it was supposed that nurses were only qualified to do first aid work in industrial dispensaries. However, the four walls of a dispensary could not confine the progressive nurse, and she soon proved her value to employers. As a result, nurses are now filling important industrial positions, in many instances having full charge of health, sanitation, employment, and general supervision of personnel.

It is therefore essential that she be a trained nurse with broad experience, plus tact and business ability, and that she constantly increase her store of knowledge in order to be able to cope with the various medical and sociological conditions which present themselves from time to time.

Industry is demanding of its executives, heads, and subheads of departments, a broader knowledge of their own particular branch of work. Resulting from this demand we find department head meetings, special conferences, conventions. Department heads as well as industrial nurses must realize the importance of similar conferences for the industrial nurse on subjects pertaining to the health and well being of their employees. A well organized industrial nurses' club will meet this need.

Help in Selection of Nurses

Many Cleveland employers are appealing to club members for help through the Club, that they may make no mistake in selecting a nurse for their industry. The Club representation at this convention is additional proof that they have recognized the benefit of our Club to employers.

We need first to consider the importance of the trained nurse in industry. As already stated, she was primarily employed for first aid work in industrial dispensaries. It is quite possible that the motive for employing a nurse was 99 per cent monetary and 1 per cent humanitarian. Regardless of the motive, the well trained nurse who wishes to serve humanity has an unlimited field in industry. Her value and her opportunities cannot be measured.

She must possess tact and an understanding of human ills, both mental and physical. Her personality must be such as will qualify her to meet people in all stations of life. She must be as ready to advise the foreign laborer as the highest executive in the organization, or *vice versa*. She should have a broad experience in her own profession, and additional training or experience in public health or social service work.

A large majority of industries employ physicians on a part time basis only, while the nurse is a full time employee. It is her duty to observe the general health of the employees, to recognize abnormal appearance, and working conditions. We all know the value of recognizing early symptoms. We know, also, that illness and general poor living habits are frequently the underlying causes of accident. It therefore becomes imperative that the industrial nurse take advantage of every opportunity to instruct in personal hygiene, thereby contributing her share to accident prevention.

The industrial nurse must be ever on the alert to recognize social problems which frequently present themselves under the guise of illness. In order to keep well informed on all subjects pertaining to her work it is necessary that she meet at intervals with those who are engaged in similar work. Discussion of the various phases of the work and their individual problems are of mutual benefit. With the enormous responsibilities of the industrial nurse, the opportunity to instruct employees along lines of wholesome living, the employees in turn giving to their families the knowledge which they have obtained, one can readily comprehend the necessity for constant study as a means of broadening her scope of knowledge through every available source. She will in this manner fulfill the highest ideal of her profession, "Service to Humanity."

DENTAL CLINICS ARE SUCCESSFUL

Dental clinics are being conducted by the Oral Hygiene Committee of the Minnesota State Dental Association in conjunction with the Minnesota Public Health Association, representing nearly every county in the State. They are held independently or with the pediatric, ophthalmic, tuberculosis, and psychiatric clinics. They are financed by the sale of Red Cross seals.

Dr. W. H. Card, chairman of Oral Hygiene Committee, writes: "It might interest you to know that since November last we have conducted about sixty-five clinics, in about thirty-five counties, at which more than twelve thousand children from five to fifteen years of age have been examined. These are demonstration clinics in which examinations are made of the children, advice is given to the parents on the care of the mouth, importance of six-year molars, how to prevent decay, irregularities, etc. In all cases children are referred to their local dentists for any reparative treatment necessary. Usually at each clinic there is arranged a lantern slide lecture to which are invited parents, teachers, and high school students. Sorry I haven't more time so that I might go into detail about our oral hygiene work, but from letters we have received, and comments we hear, we believe we have done a great deal of good in the short time we have conducted our clinics.

"The nurse, no matter what branch of her profession she may follow, on account of her close relation with the patient, can do much to spread the Gospel of Oral Hygiene, and impress upon the patient the close relation of teeth to health. A wonderful field is open for the dental nurse in public health work, especially institutional work."

WHAT MAN IS MADE OF

According to the *Minnesota Public Health Association Journal*, the average man contains the constituents found in 1,200 eggs, has iron enough to make four tenpenny nails, fat contents to make seventy-five candles and a good sized piece of soap, not to speak of a bowl of sugar. Considering that eggs are selling for 95 cents a dozen, matches at 6 cents a box, and candles for 5 cents each, $582.84 is the actual worth of the constituents of a grown person, to say nothing of what the sugar he contains may be worth.

THE RELATIONSHIP OF RURAL RECREATION AND THE PUBLIC HEALTH NURSES

By E. C. LINDEMAN, Chairman of the Committee on Recreation, American Country Life Association

THERE are two distinct schools of thought in the American country life movement. The "economic" school believes that rural life will be satisfactory when a sufficient economic reward is assured to the farmer for his labor. The "social" school insists that mere economic success will not assure social success; that material progress, when separated from social and spiritual progress,

"Going to the Show!" is the modern American slogan. And going to the show now means sitting lazily in a half lighted room while highly emotional scenes of the unreal phases of life pass before the sight and make their impression.

does not produce a contented and constructive population.

The public health nurse is now an integral part of the American country life movement. There are approximately four hundred public health nurses now functioning in rural areas. What impetus will these new professional leaders give to the country life movement? Will they emphasize health *per se*, or will they see health in its relationship to the whole of life? Are they to promote the "particularist" or the "social" viewpoint?

The answer to these questions is vitally important. If we are to go on with each agency and each school of thought laying stress upon its program as the sole solution of the country life problem, there can be only one result, namely, confusion and lack of real progress. The American Country Life Association was organized for the primary purpose of presenting a united front of progress. It does not overlook the necessity of a sound economic basis for agriculture; it holds, however, that the economic well being must be supplemented by education, health, recreation—those elements of life which need to be added to material existence in order to distinguish man from animal.

This Association is organized on the basis of standing committees, each of which has a particular phase of country life for its intensive study. The author is associated with the Committee on Recreation, and it is in this relationship that this article appears.

What Is Public Health?

Before a statement regarding the relationship between recreation and the public health nurse can be justly made it is essential that the full implications of public health be reiterated and stressed. There is perhaps no more adequate definition of public health than that proposed by Dr. C.-E. A. Winslow of the Yale School of Medicine.

Public health is the science and art of preventing disease, prolonging life, and promoting physical health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organization of medical and nursing service for the early diagnosis and preventive treatment of disease, and the development of the social machinery which will insure to every individual in the community a standard of living adequate for the maintenance of health.

This definition includes two functions of public health organization which have a bearing upon the problem of this paper. If public health is to "prevent disease, prolong life" and "insure to every individual in the community a standard of living adequate for the maintenance of health," it must certainly include within its scope those activities which achieve these ends. The difficulty in including recreation as a prerequisite to or as an integral part of the public health program arises through the lack of correlation between the physical and the social sciences. When some advocate of the so-called "new public health" writes a book in which he says: "A bullet will travel equally as far through the soldier who is physically perfect as through him who is a physical wreck," it confuses the social scientist.

The Rural Community has this recreational advantage: There are abundant places to play. The utilization of these rural community resources awaits only an awakened and earnest leadership.

Folk dancing utilizes the finer accessory muscles. It co-ordinates muscles with the nervous system. Rural children need this particular type of recreation because farm work over-develops the major muscles.

However, the correlation between the physical sciences and the social sciences must be made, else science itself will be placed in an absurd position. And Dr. Winslow, in his definition of public health, leaves room for the sociologist and the economist to add his contribution.

Equally important is it to have a clearly defined idea of the nature and the purpose of recreation in life. In the broadest possible sense, any activity which a person will continue to engage in without hope of pecuniary reward may be called recreation. A more specific definition of recreation might be stated in this form: Recreation combines those activities of life which are physically energizing and joy-producing. Mere exercise is not play, as every farm boy and girl knows full well. Play is spontaneous expression of the fullness of life.

Constructive recreation:

(1) Is physically energizing. It rejuvenates the muscles.

(2) Promotes mental alertness. It develops the sense perceptions.

(3) Promotes sociability. People who play constructively love their fellow men.

(4) Is joy-producing. Play is the natural antidote for melancholy and sorrow.

(5) Makes good behavior habitual. Behavior is translated in terms of muscle-action through play.

The Problem of Rural Recreation

Why do the people of the open country need a recreational program of activities? They have the open air, the fresh food, and the wholesome work of the farm. Despite all of these apparent advantages, the fact that the rural people are not superior in health to city people is well known. It is needless to recapitulate here the numerous studies which bear out this statement. The important consideration for the public health nurse is: What are the deficiencies of country life? And how are these deficiencies related to health?

Farm work and farm life in general presents the following issues: (1) The ordinary work of the farm develops the major muscles but does not develop the finer or accessory muscles. In order to secure symmetrical development there must be a supplementary regimen of recreational activities which will utilize the finer muscles. (2) There are certain forms of farm labor, usually carried on by women and children, such as cotton picking, beet weeding, onion weeding, *et cetera*, which are not merely inimical to symmetrical bodily development but which are actually deleterious to health. (3) There is a lack of sociability or opportunity for sociableness in country life which tends to develop a somber or non-optimistic outlook on life. A sociable use of leisure hours is the only feasible corrective.[1]

Our larger cities are no longer negligent in providing recreational advantages. The playground movement has been peculiarly a city movement. The same public opinion for recreation does not exist in the open country. The reasons for this are:

(1) The play movement has not been carried to country people.

(2) Country people do not understand the function and purpose of play in modern life.

(3) The agencies promoting play in the country have been largely institutional in their approach.

(4) The normal play groups in rural communities are often too small to encourage group recreation.

(5) Country children have been too often regarded as economic assets to the farm.

(6) Country people have assumed a lack of leisure time.

(7) The cheaper forms of amusement of the city have been at work in rural communities destroying the taste for constructive, purposeful recreation.

All of the above may act as a discouragement to the public health nurse or rural leader who sees the need of recreation. It should serve in the opposite direction; it should act as a mighty challenge; for there are advantages in country life which cannot be matched by the life of the city. Farm life builds a foundation for physical health in the major muscles; the rural family has not suffered as much disintegration as the city family; the leisure hours of country people are not consumed by multitudinous activities; commercialized amusements have not yet obliterated the taste for wholesome recreation; and, finally, the children of our Nation are there. In spite of the increasing disproportion between rural and city populations, the country still remains the seed bed of our population. Nearly two-thirds of our children live

"Man is Whole Only When He Plays." When men and women stop playing they have lost the zest in life. Rural recreation should be planned to interest the old as well as the young.

[1]For a fuller discussion of this and other phases of the problem of rural recreation see "Recreation and Rural Health," second annual proceedings of the American Country Life Association.

The seven children in this family do not live in the slum district of a large city. This picture was taken in a small rural village. Every member of this family is diseased or has prominent physical defects.

in villages and towns which are rural or in the open country.

The Recreation the Country Needs

On the basis of years of observation and experience the author ventures to state some of the characteristics of good recreation for the rural population.

1. Games used should be *safe for health*. This does not mean that they are not to involve physical risks; it does mean that they must be games which do not involve unnecessary heart strain and which may be played under hygienic conditions.
2. Types of recreation in which old as well as young people may take part should be encouraged. The country community is made up of family units.
3. Types of recreation suitable to both sexes should be utilized, for the same reason as stated above.
4. Types of recreation requiring a minimum of equipment should be encouraged. Expensive play equipment is not essential to a constructive recreational program.
5. Games which develop cooperative action should be used.
6. Types of recreation adapted to large numbers as well as small numbers should be used.
7. Types of recreation should be encouraged that will serve to offset some of the deficiencies of country life enumerated in the earlier part of this article.
8. Every rural gathering should be regarded as an opportunity for promoting right types of recreation.

Aids to the Public Health Nurse

There are grounds for believing that the public health nurse stands in a strategic position in regard to the rural recreation movement. She is not using recreation merely to build up an institution. She is sincerely interested in the well being of the people with whom she serves. She has a fundamentally sound reason for promoting recreation, for it is through her that mental and physical health is to be democratized. It is not to be expected that the public health nurse is to become the recreational supervisor for her county or community. She is, rather, to be the initiator, the teacher, the social worker who sees recreation as a part of the whole of a well ordered life. With such a viewpoint she may exercise a far reaching influence on the issues of rural recreation through activities such as:

(1) Nutrition clinics where certain physical defects are revealed.

(2) Medical examinations where further physical defects are revealed.

(3) Detection of processes of degeneration due to improper use of leisure hours.

(4) Promoting respect for the human body through the play ideal.

(5) Supplementing farm life with those activities that will invigorate and enthuse as well as correct deficiencies.

(6) Demonstrating play activities as correctives and as a part of preventive medicine.

In this manner the public health nurse renders the greatest possible service, in that she demonstrates the real need for recreation. If we have sufficient faith in people we may be assured that when a vital need is effectively demonstrated, means for meeting the need will be devised. When this point has been reached, the public health nurse may act as the social engineer who assists in constructing the machinery which will provide wholesome and adequate recreation for each community in which she functions.*

REPORT OF WORK FOR THE HANDICAPPED

A report of three years of work for handicapped men by the Institute of Crippled and Disabled Men of New York City has just been published. This report gives a brief summary of the work of the Institute, including its medical work and the different kinds of vocational training offered by the Institute. The Institute has had considerable experience in rehabilitation and the report of its three years pioneer work should be read by all who are interested in this new humanitarian work. The Institute has not limited its activities to vocational education but has taken the word "Rehabilitation" to mean "The use of suitable means for rendering a disabled person again fit to earn his living."

HEADACHE AS A DANGER SIGNAL

The *New York Times* quotes at length from an article by Dr. A. E. Herr of Cleveland in the *Western Medical Times* on "Headache as a Danger Signal." "Headaches are useful," said Dr. Herr. "They are only the red flags hung out as a sign that some organ is functioning abnormally. They are not diseases but always symptoms. A headache has virtue because it leads you to search out the causative factor. It is not an enemy, but a friend."

Dr. Herr takes the position that the majority of headaches are of that class which have their genesis in wrong living and wrong habits; so that in the great preponderance of instances a mere correction of the irregularity will relieve the headache.

"Considerable can be learned as to the source of the trouble by its relative location in the head," he writes. "For instance, the majority of people are aware that an ache in the forehead is usually due to disorder of the stomach or bowels, but if situated to one side in the region of the temples and coming on more or less periodically, it indicates some error in refraction which can be corrected by the wearing of a proper lens."

*For concrete directions for games, organization, *et cetera*, see Bulletin prepared by the author for the American Red Cross. This may be obtained through Mr. E. L. Morgan of the Rural Service Division, National Headquarters.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

CONSULTATIVE COUNCIL ON MEDICAL AND ALLIED SERVICES

THE Consultative Council of the Ministry of Health has issued recently an interim report on the future provision of medical and allied services. Dr. Addison, the minister of Health, in October last requested the Council to consider and make recommendations as to the scheme or schemes requisite for the systematized provision of such forms of medical and allied services as should, in the opinion of the Council, be available for the inhabitants of a given area. This interim report sets forth the trend of the Council's deliberations and conclusions and provides highly suggestive, interesting, and instructive reading. Emphasis is laid, in the first place, on the fact that the changes advised in the report are rendered necessary because the organization of medicine has become insufficient and because it fails to bring the advantages of medical knowledge adequately within reach of the people. It is pointed out, what is quite obvious, that preventive and curative medicine cannot be separated on any sound principle and in any scheme of medical services must be brought together in close coordination. Also, and this is a very important point, they must be brought within the sphere of the general practitioner.

The services are classified into those which are domiciliary as distinct from those which are institutional, and those which are individual as distinct from those which are communal. The domiciliary services,—those of the doctor, dentist, pharmacist, nurse, midwife, and health visitor,—constitute the periphery of the scheme, the remainder of which is mainly institutional in character. The health centers which are suggested and which are the main props of the scheme are institutions wherein are brought together various medical services, preventive and curative, so as to form an organization.

Health centers may be either primary or secondary, the former denoting a more simple, and the latter a more specialized service. The primary health centers are institutions equipped for services of curative and preventive medicine to be conducted by the general practitioner of that district, in conjunction with an efficient nursing service and with the aid of visiting consultants and specialists. Primary health centers would vary in their size and complexity according to local needs, and as to their situation in town or country; but they would for the most part be staffed by the general practitioners of their district, the patients retaining the services of their own doctors. The distinguishing feature of the primary health centers in contradistinction to secondary health centers would be that they would be staffed by general practitioners. Hospital facilities would be provided; there would be wards of varying sizes, and for varying purposes, including provision for midwifery. The increasing employment of open air treatment of illness would be provided for. Clinics would be equipped where doctors could see their patients and consult with one another. The primary center would be the home of the health organization and of the intellectual life of the doctors of that unit. Those doctors, instead of being isolated as now from each other, would be brought together and into contact with consultants and specialists; there would develop an intellectual traffic and a *cameraderie* to the great advantage of that service.

Secondary health centers must be situated in towns where an adequate equipment, an efficient staff of consultants and specialists, and the necessary means of communication can exist. The services of the secondary centers would be mainly of a consultative nature. The centers would receive cases referred to them by the primary centers, either on account of difficulties of diagnosis or because in their diagnosis or treatment a highly specialized equipment was needful. On the other hand, primary centers would ease the work of the secondary centers by treating less complex cases which are now sent to the larger hospitals, and by receiving patients from the secondary centers when the acute stage of their illness had passed. A secondary health center should be completely equipped, since on the excellence of its service and organization the efficiency of the primary health centers and domiciliary services based upon it would, to a large extent, depend. Secondary health centers should in turn be brought into relation with a teaching hospital having a medical school. This is desirable, (1) in the interests of the individual patient, that difficult cases may have the advantages of the highest skill available; and (2) in the interests of the medical men attached to the primary and secondary centers, that they may have the opportunity to follow the later stages of an illness in which they have been concerned at the beginning, to make themselves acquainted with the treatment adopted, and to appreciate the needs of a patient after his return to his home.

The drawers up of the report state underlying their recommendations is the dominant purpose of providing the best services for the health of the people. Their recommendations are designed to secure: (1) Provision of

buildings and equipment. (2) Services suitably correlated and available for all. (3) Opportunity for the best work and the furtherance of knowledge. (4) Coordination of preventive and curative medicine. (5) Freedom of action for doctor and patient. Under existing conditions doctors are frequently without such provision or opportunity; they have imperfect access to such resources as those of bacteriology, biochemistry, radiology, electrotherapeutics; and they have inadequate means of assistance from consultants or specialists. Consequently they cannot always do justice to their patients or themselves.

The scheme outlined is bold, ambitious, and widely comprehensive in its scope. Some may and have called it Utopian, but a more fitting term by far is idealistic. It is not so impractical as it appears on first consideration. The character of medical practice is changing. It is now, or will be in the not far distant future, preventive rather than curative and the scheme is in keeping with the change. Further, the principal, indeed the only means for preventing disease on a large scale is early diagnosis, and it has been but recently recognized that the general practitioner is the sole individual who has the opportunity for this kind of research. Hitherto the means for undertaking work of this character have been denied him. The establishment of primary health centers will remedy this state of affairs. The cost need not be so staggering as at first sight it seems it must be. Organization and coordination will do much to render the cost of establishing primary health centers not too oppressive. The secondary centers need not be established at first. If the scheme of the primary health centers is efficiently carried out, it will be for the good of the individual and public health, and of the medical man. By the mere publication of the Report the Council has done the cause of health an inestimable service. It has stimulated the imagination and should incite those interested in such matters in all civilized countries to healthy emulation.

LONDON CORRESPONDENT.

MENTAL DISORDERS AND VOCATIONAL RE-EDUCATION

BY EUGENE N. BOUDREAU, RECENTLY ACTING ASSISTANT SURGEON, UNITED STATES PUBLIC HEALTH SERVICE, NEURO-PSYCHIATRIST, FEDERAL BOARD FOR VOCATIONAL EDUCATION, DISTRICT NO. 2, NEW YORK, SYRACUSE, N. Y.

IN the past two decades much progress has been made, especially in America, in the study and understanding of mental disorders. Increase in knowledge and interest have fortunately done much to improve the public attitude towards unfortunate persons whom life has afflicted with these maladies. In addition the knowledge gained through recent work, clinical and laboratory, in psychiatry and psychology was immediately practical when the war developed and it became apparent that mental and functional nervous disorders would constitute a medico-military problem of the first magnitude. Yet it took England and France some time to develop a method of handling the situations which arose from placing too great a burden upon constitutions not sufficiently endowed mentally to bear it. Both of these nations had some unhappy experiences and found that shooting was not a cure for epidemics of war neurosis.

All Nations Unprepared

Dr. McCarthy, the Philadelphia neurologist, says that the Germans also were entirely unprepared for the multitudes of war neuroses in the early period of the war. Their inelastic minds and inelastic system were still groping with the problem unsuccessfully when, while on a mission from the United States government just preceding our entry into the war, he had the opportunity of observing Germany's war machine. America was more fortunate because in this field she had the experience of the other belligerents to build upon. Here, as rapidly as possible after war was declared, a force of neuropsychiatrists was marshalled; some were sent to England to learn at first hand the practical methods of managing the problems there; others were assigned to keep an expert eye upon the officers' training camps, and, finally, complete boards were placed in each cantonment to eliminate as many as possible of those unsuited to meet war at close range. At the same time an organization was being developed to cope with the situation in Europe when our troops entered the combat actively. Thus, within a year from our declaration of war, there was in France a trained neuropsychiatrist with every tactical division sent overseas, one or more at every hospital center, and a chain of neurological hospitals reaching from the triages at the firing line, where the division specialist functioned, to the base port, where the unrecovered cases were finally evacuated to the United States. Each one of these stations acted as a valve or perhaps better a sieve the chief function of which was to save as many of these cases as possible for active combat. But the operations before Chateau Thierry found the system too undeveloped to dam the flood of nervous soldiers which in every army and in every action flows backward from the firing line. The result was that four thousand cases of reported "shell shock," 10 per cent of the total casualties, had been scattered like feathers before a wind to the already over-burdened general hospital system when that initial battle was ended.

The Prejudice Against Psychiatry

It will never be generally known what prejudice against neuropsychiatry each specialist had to overcome among old-time military men of the line and medical officers new to the demands of modern warfare; but be it said to the credit of both, and the force organized by Col. Pearce Bailey and Col. Thomas W. Salmon, the first working at home and the latter in the American Expeditionary Force, that, when the armistice was signed there was unanimous cooperation from all and this had become one of the most firmly established and best trusted special organizations.

In the St. Mihiel and Argonne offensives there was no repetition of Chateau Thierry. The special machinery was then fully organized and working smoothly so that 90 per cent of the neuroses cases reaching the triages were returned to combat from the various stations along the way back to Base Hospital 117. Only 10 per cent reached the base port for return to the United States. In

all, from the first days of training until the final evacuation of France by American troops, less than three thousand cases of functional nervous diseases were sent home for further treatment or discharge for disability. After the armistice the system was extended and followed the Third Army into Germany under the direction of Dr. Samuel W. Hamilton, Consultant in Neuropsychiatry for the Army of Occupation. Centers were established at Coblenz and Trier to work in conjunction with the division psychiatrists and to handle cases that could not be handled in the division hospitals. These units remained in Germany as long as troops remained in any numbers. As rapidly as possible neurologists trained in France were returned to give the advantage of their experience in the after-care of these more unfortunate soldiers who were and are still in the hospitals of the United States. On their way to the United States these experts had charge of convoys of mental cases, thus insuring expert supervision of the care of mental and nervous cases until the home ports were actually reached. Therefore, from the time of his entrance into the Army until his discharge our soldier had available the knowledge gained through the past two decades of mental research.

Care for the Mentally Wounded

Now what is being done for our mentally wounded soldier since his discharge from the army? Are there many such who are now handicapped for the new battle that against changed conditions which are a test of strength for the most normal man discharged from that army of four million? What can be done for them? What agencies are working to discharge our debt to this class of wounded men? Whatever be the attitude toward some or of all such men, it is more than certain that had not Germany menaced the safety of our American birthright and had not these men been removed from the security of a manageable environment, they would not now be mentally incapacitated. Our duty is therefore clear. As to the number of such cases, no adequate estimate can be made. We have definite information only of those whose endowment was so overtaxed that they are now in hospitals, forever incapable of helping themselves because suffering from incurable psychoses. This discussion is not especially concerned with these. It is with those who temporarily broke down and who were later returned to the firing line or other essential war duty by proper treatment that we are concerned. These men are comparable to the men with physical wounds returned to duty after a period of treatment. Only time and the exigencies of life will bring them forth, the aftermath of war.

What can be done for them? Much in the way of smoothing their way now and endowing them with new resources by training for vocations that will use their faculties to the best advantage. The best authorities will agree upon this. To illustrate: Many individuals who have by the stress of training or of fighting and because of the sudden change of environment from such as that of a salesman or bookkeeper earning $25 to $40 a week to one of the soldier of the line or the recruit in training who faces the prospect of war in all its present terrors, developed a mental disorder, and recovered. Now the war is over; they have been discharged to look after themselves. Conditions are much changed. They have lost contact with their old ways of living just long enough to make another adjustment necessary. This, together with the need of immediately making a living, taxes their lowered mental tone which is often below its power of responding. They become depressed, cannot continue at work because of lack of power of concentration, begin to feel weak, are restless, and finally entirely unable to "carry on." It is then that such men come to the attention of government authorities. Are they malingerers, to be driven out in scorn, are they "weaklings" beneath the consideration of a generous government, or are they human beings who by patriotism, idealism, or compulsion were brought into a situation to which they were unable to adapt? Are they not definitely casualties of war? That type of case will be helped by vocational training, for it will tide them over a difficult period of adjustment.

Delays Increase Difficulties

The government agencies now dealing with these cases are the Bureau of War Risk Insurance and the Federal Board for Vocational Education. To the latter falls the duty of rehabilitating wounded soldiers and other service men. Is it their duty to rehabilitate these nervous invalids? The answer is obvious, but the rehabilitating of these invalids is one of the most difficult problems the Board will have, and can be solved only by attacking it quickly and with a will. To delay will only be to increase the difficulties, and the ultimate cost.

Nearly two years have passed since the Federal Board for Vocational Education was given the function of rehabilitating our soldiers who were incapacitated by military service. Up to the present time this Board has adopted no policy regarding the management of mentally invalided individuals, nor until recently has the Bureau of War Risk Insurance. In consequence they have been shunted back and forth between these two organizations.

The District Office of the Federal Board in New York City seems to have been the first to have neuropsychiatrists working as examiners in the office. From material made available by this work it has been found that in a group of ninety-five cases examined and having present nervous disorders, they were diagnosed as follows:

Psychoneurosis	38
Mental Defect	12
Psychoses	10
Constitutional Psychopathic Inferiority	6
Epilepsy	11
Organic Nervous Disease	9
Cerebrospinal Syphilis	2
Endocrinopathy	5
Chorea	5
Gluteal Myositis	1
	95

Roughly, 75 per cent of this group were also found to be suitable for training according to the rules established by the Federal Board for Vocational Education, that is, an abnormal condition now present must be shown to be traceable to service or to have been aggravated by service; and training must be shown to be now practical or feasible. Discussing the conditions tabulated above from a medical aspect, the Federal Board viewpoint, and also in the light of experience obtained in government hospitals caring for similar ones and contact with them in the examining room of the Federal Board, my views regarding them may be summed up briefly as follows:

Retraining an Advantage

Of the psychoneuroses, most cases when properly selected by competent neuropsychiatrists can be trained to advantage. As indicated above, the condition first developed under the stress of military service and was relieved

by treatment. When, however, these men meet the difficult situation of making a new adjustment at discharge, accentuated at present by high living cost, they often relapse, or perhaps show that there has never been entire recovery. Relief from the financial stress and interesting occupation will without doubt help them on the road to rapid recovery. However, it is essentially improper to train these cases for more than one year or to encourage the idea of a longer period. Their vocational education must be under the direct supervision of men trained in dealing with functional nervous disorders.

Of the psychoses, only those of mild type appear for training; the more severe types are in Government or other hospitals. In the case of men with mild depressions, again relief from financial worry, together with occupation having a practical object, affords a diversion from brooding and depressive introspection, and a positive aid in treatment. In *dementia praecox* of the mild types, men can often be benefited by vocational training for simple pursuits. They can be made self-supporting and "social recovery" attained. Such cases frequently show little change over a period of years and can be made useful members of society. We have many of them about us in everyday life for whom allowances are commonly made for their peculiarities so that they do fairly well.

Mental defectives were, of course, not necessarily changed much by military service, except that because of their mental defect they adjust to changes badly. Consequently the change from civil to military life and back again may bring about difficulties and distress, such as development of a secondary mental disorder or a complete inability to meet the changed conditions. So in a measure such cases may be said to be also eligible for vocational training of a highly specialized type, supervised by those with special knowledge of mental deficiency and its practical management. Such training is also feasible in simpler pursuits, or some individuals may have special gifts which can be developed advantageously.

Policy Toward the Inferior

Of the constitutional psychopathic inferiority cases, all existed prior to service. Many were soon discharged at the camps because of inaptness for military duties of any sort. They did not do well before entering service and probably will not now. A determination of policy, however, should be made regarding this type, for they are rather frequent, nearly 6 per cent according to data above. It is certain that such a person without a useful trade is more likely to manifest anti-social conduct than one with a trade.

In the case of epileptics, in my experience, many have developed in service, if our information is dependable. It is not improbably so in most cases, hence they should have consideration. Few of the cases I have seen are institutional cases, most of them having only infrequent attacks. At best treatment usually only decreases the frequency of attacks. Yet they may be useful economically for a period of years. From a cold economic aspect such men should be given the advantage of some training to put them into a way of living which will make them economically profitable to the community for a longer time. From a humanitarian aspect, we cannot neglect them. Their disease was hastened by the stress and excitement of combatant or non-combatant duty; therefore, the Government is responsible to that extent, and must meet it.

Under the head of organic nervous disease above listed are grouped the brain injuries and peripheral nerve injuries. The latter give little difficulty, for the condition is definite, the degree of disability easily determined, and the diagnosis not questioned; but in cases of brain injury, whether resulting from direct or indirect cause, there is great improvement after a period of treatment and convalescence. No objective signs of the past trouble may exist and yet we know that individuals in civil life thus affected often show subsequent personality changes, have lessened mental power, or lose moral tone, become inefficient, and often end as vagrants. Brain surgeons tell us that such cases, though showing no neurological signs in ordinary examinations, have increased cerebrospinal fluid pressure, as indicated by manometer reading, and also slightly blurred optic discs. One New York school of brain surgeons advocates decompression operations when those signs are found and claims satisfactory results in improvement of the deteriorated personality. Among the few cases of brain injury I have seen, the men almost invariably claim some subjective changes. It seems almost inconceivable that such grave cerebral disturbance can occur without residual damage. May not, therefore, such cases have just claim for vocational training?

Loss of Endocrine Balance

Finally, there are many men in whom the sudden change from a sedentary or semisedentary life, to the drill field and the march, brought changes in the endocrine balance, especially of the thyroid secretions, with their concomitant symptoms of nervousness, rapid heart action, dyspnea on exertion, tremor, and exhaustibility. Such cases were well known to all medical officers in all armies. All of them that it has been my privilege to see returned to civil life were in sad plight. Unfortunately, theirs is a permanent condition requiring strictest regulation of habits if life is to be made at all endurable. They undoubtedly should be trained for some light occupation requiring a minimum of physical or mental strain.

The ideal system would be to have several centers, to which these men would be sent, where under judicious medical control they could learn painting, bookkeeping, or could become machinists or farmers without waste of time, and where, likewise, they would receive proper psychotherapeutic treatment. However, this plan is said to be now impractical; first, because the plan is too expensive; second, because the Government has no legal control of the individual; and lastly, because too much time would be required to develop such a plan.

Offers a Practical Solution

The most practical scheme would be to adopt the machinery available at present, by securing the cooperation of the War Risk Insurance Bureau, for that organization is struggling with another phase of the same problem. It is, however, rapidly developing a social service system and is about to open out-patient clinics for these cases. By using these agencies and the means already developed, a system of training under careful follow-up methods and suitable medical supervision ought rapidly to develop with little comparative expense and no waste of time.

In offering these suggestions there is but the one purpose in view—to forward the interests of a group of men with whom I have been in contact for more than two years and whom I have seen in the camps at home, in the hospitals of France, on the firing line, and, finally, again struggling with their problems in civil life. To these men, knowing them as I do, my sympathy is attached and it is my ambition to see that Government for which, notwithstanding their lack of certain native endowments in the mental field, they willingly gave their health and happiness, discharge its duty to them.

THE PROBLEM OF DISEASE

From a report by the Public Health Committee of the New York Academy of Medicine, New York City.

THERE was no one illness that was treated exclusively in the dispensary except two cases of jaundice which happened to be so cared for. Conditions where more than one-third of the cases were under treatment in the dispensaries were as follows:

EXCLUSIVE CARE IN DISPENSARY

	Cases in Dispensary	Total No. Cases	Per cent
Eye Diseases	33	55	60.
Ear Conditions	4	11	36.3
Nose Conditions	1	2	50.
Genito-Urinary	3	7	42.8
Boils	2	5	40.
Abscesses	8	20	40.
Eczema	3	8	37.5
Infections	6	18	33.3
Other Skin	8	11	72.7
Minor Surgical	8	18	44.4

This table is significant. Almost all of the conditions mentioned in it require the services of specialists. On the other hand, conditions which occurred among the families in the survey and which did not come at all to the dispensary were: diabetes, malaria, neuritis, neuralgia, gall stones, and a few others. In eleven instances the statement was made that the dispensary was used in cases of contagious dieease.

As previously stated, the share the dispensaries take in meeting the problem of disease among the self-supporting workingmen's families has in all probability been understated for two reasons: (1) The use made of the dispensary in certain minor conditions was probably forgotten, as were the illnesses themselves; and (2) the available dispensary facilities in the boroughs outside of Manhattan and Brooklyn are meager and, as an appreciable proportion of the families in the survey lived outside of these boroughs, and as a considerable group of the total number of families were Slavic and Italian, who make slight use of dispensaries, the aggregate use of dispensary reported was under the circumstances an underestimate.

With a view of ascertaining how the different nationalities treat minor illnesses three conditions very commonly reported, such as colds, stomach trouble, and "being run down," were classified by type of treatment according to nationality (Table XIV). Very few of such cases, a little over 1 per cent, went to the hospital; 12 per cent went to the dispensary; while 39 per cent consulted a private physician. The native born used the dispensary for one-fourth of these three more common minor illnesses; the Hebrews for more than one-fourth; the Irish for 14.3 per cent. the Negroes for 11.9 per cent; the Germans for 8.9 per cent; the Italians for only 4.4 per cent; the Slavs for less than 2 per cent. The native born employed private physicians and consulted at the dispensary for exactly the same number of cases. The Hebrews employed private physicians in almost 40 per cent, and the Slavs and Italians used the private physicians in more than half of the cases. Of those who did not trouble themselves about professional medical care, the miscellaneous group and the Irish head the list, with the Germans, Negroes and native born following. The least neglect was reported among the Hebrews.

As seen from Table XV the ratio of complete to partial incapacities was different in each of the several racial groups. The two groups which showed the highest number of cases of partial incapacity per thousand were the native born and the Irish. These two groups show the largest use of the dispensary, while the nationalities that show the least use of the dispensary, like the Italian and Slavs, had the lowest rates of partial incapacity and the highest rate of complete incapacity. On the other hand, the Hebrews, who use the dispensary very liberally, showed a low rate of partial incapacity and a high rate of complete incapacity.

From the analysis of the foregoing facts the apparent inference is that the racial attitude has the most important bearing on the use of dispensaries and other medical resources. The Hebrews are more concerned about obtaining medical treatment than any other of the groups, and they use the dispensary to a larger extent than the others; while the Slavs and Italians, although not as neglectful of their condition as some of the other racial groups, are utilizing medical institutions to a very slight extent. The lack of adaptability to American life

TABLE XIV.—AGENCIES EMPLOYED IN THE CARE OF PATIENTS COMPLAINING OF COLDS, STOMACH TROUBLE, OR BEING "RUN DOWN," TABULATED BY NATIONALITY

Nationality	No. of Cases	Hospital		Dispensary		Private Physician		Lodge or Society Doctor		Non-Professional Care	
		No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent
U. S. A.	132	1	.8	32	24.2	32	24.2	2	1.5	65	49.3

and the difficulty of understanding English are the two most important causes for this phenomenon.

Each family interviewed was questioned as to why they have used the dispensary; or why they do not use it if they never had applied for ambulatory treatment. Four hundred and nineteen families stated their reasons for using the dispensary and 870 gave reasons why they do not use it. Of those who were using the dispensary, 52.4 per cent said that they went because they liked the treatment given; 0.5 per cent because they required serv-

ices of specialists which they could not otherwise obtain; 14.3 per cent stated that the lack of funds was the reason. In 17 per cent convenient location was the determining factor; 15.6 per cent were referred by friends or the school nurses, or came to get the baby vaccinated. Of the 870 who gave reasons for not using the dispensary, 266, or 30.6 per cent, said that they were able to pay private physicians and 263, or 30.2 per cent, stated that they never had occasion to use the dispensary. Eliminating these two groups of 529 families from consideration, the reasons given by the remaining 321 families were as follows: 76 of them had never heard of a dispensary, the Slavs being the predominating element in that group; 49 said they were afraid of dispensaries,—here the Italians were the predominating element; 78 stated that they were dissatisfied with former treatment; 11 did not use dispensaries because they could not speak English, 45 because they would lose social prestige, the native born leading in this group (Table XVI).

It may be of interest to quote some of the statements made expressing the attitude of the people toward the dispensary.

The chief faults found with the dispensary are the long waiting time, hurried procedure, and the lack of personal interest taken by physicians; also abruptness in dealing with patients.

"Half the cure is in kind of doctor you have. Seven years ago I was at Demilt for rheumatism and liver, made two visits but prefer private doctor" (Irish).

'Four years ago went five or six months to Roosevelt for stomach trouble—think it saved my life" (German).

"Father would go to dispensary if open at night and if he did not have to waste so much time there" (Italian).

"Goes to Columbus Hospital because that is an Italian hospital and his own doctor belongs there" (Italian).

"Likes to be treated by more than one doctor" (Italian).

"Thinks people do not get proper attention. Prefers private doctor" (Hebrew).

"Cannot leave smaller children alone for so long a time" (Hebrew).

"We call the doctor—feel that free patients do not receive attention or care" (Miscellaneous).

"Patients would really like to know what is the matter with themselves but they have to wait an awful long time, from one to four P. M., just to have the doctor see you for five minutes" (Miscellaneous).

"Was three or four times—did not like it at all. They never tell you anything, and why should they not?" (Miscellaneous).

"In dispensaries you have to sit around and wait so long that one gets a cold and does not know what else he can catch. Doctors want to experiment on those poor patients and have no time or interest to follow up cases, except Dr. C., who certainly did help" (Miscellaneous).

"Went to dispensary for ear trouble—but there was such a crowd that she could not be taken care of—would go if opened in evening" (Miscellaneous).

"Married daughter is going to dispensary now for throat trouble, and likes it very much. Pay $1 each time (?) and for medicine. Family never call in doctor, always try to cure themselves" (Italian).

"Constant dispensary care for minor ailments keeps her family in good condition" (Italian).

Duration of Illness and Cost of Treatment

The data on the duration of illness are so unsatisfactory that no attempt was made to tabulate them. The

TABLE XVII.—AMOUNT PAID FOR MATERNITY CARE, TABULATED BY TYPE OF CARE—NEW YORK CITY, ALL NATIONALITIES.

Total	41	10.8	5	1.2	142	36.6	88	22.6	26	6.7	32	8.2	10	2.6	6	1.5	8	2.0	29	7.4	387

information secured as to the amount of money spent during the year for medicines and treatment either at home or in hospitals is likewise fragmentary. The information for 56 per cent of the families in the lowest economic groups (A and B), which is more or less accurate, shows the following disbursements for medical and other kind of treatment during the year 1918: 16.8 per cent of the families spent no money on treatment; 37.0 per cent spent under $11.00; 19.5 per cent from $11 to $20; 10.8 per cent from $21 to $30; 7.6 per cent from $31 to $50; 2.4 per cent from $51 to $70; 0.8 per cent from $71 to $90; and 5.1 per cent $90 plus.

These disbursements include the costs in connection with childbirth. The information secured with reference to costs in maternity cases is more definite than the rest of the material bearing on the cost of treatment, and is offered herewith separately.

It shows (Table XVII) that 10.8 per cent of the maternity cases received care during childbirth free, either in institutions, or from visiting physicians sent from institutions; that 36.6 per cent of the cases paid from $6 to $10, and 22.6 per cent from $11 to $15. Only 10.7 per cent of the families paid between $21 and $30 per case, and 3.5 per cent more than $30. In the group of 88 cases in which the expenditure was from $11 to $15, the doctor was in attendance in 19; in the next higher group, 10 out of the 26 were private physicians' cases, and 5 women were confined in hospitals; while in the group expending from $21 to $25, 30 out of the 32 cases were under the care of private physicians. In families spending more than $20 per case of childbirth the midwife was employed in only a very small percentage of cases.

(Concluded.)

THE DEMAND FOR MEDICAL AND PSYCHIATRIC SOCIAL WORKERS

By M. A. CANNON, Director, Social Service Department, University Hospital, Philadelphia, Pa.

TRULY the harvest is plenteous but the laborers are few in the field of medical and psychiatric social work. Fifteen years ago a department of social work in a hospital was unheard of, and "social psychiatry" had not been invented. Now there are more than three hundred hospital social service departments in the country and hospitals not yet so equipped are in increasing numbers seeking trained workers to start new departments. As for psychiatry, it is now generally recognized to have given a new method and a new point of view to social work of all types; its methods are constantly being applied in new fields, and workers with training in psychiatric social work are more and more in demand.

An Adjunct in Diagnosis

There are several reasons for the rapid growth of social work in hospitals. It makes for economy in medical and administrative practice, by supplying the extra hospital inquiry and adjustment necessary to the securing of desired results in many cases, and the enlightened hospital recognizes this economy. Moreover, many physicians use the department of social work as an adjunct in medical diagnosis and treatment, depending upon it to get information as to living conditions and social experience of patients and to carry out in detail directions as to food, rest, exercise, work, recreation, and change of environment or habits.

There is an increasing community interest in everything pertaining to the public health and the community is beginning to see the social service department as a public health agency and to ask that it form a part of hospital equipment.

Medical and psychiatric social work is also finding its use in industry as a part of employment management, and here it promises to demonstrate a value which at least in part can be measured in dollars.

And, finally, as a branch of the profession of social work this casework with physically and mentally sick people offers an opportunity for study of social diagnosis and social treatment which social workers in the older branches have recognized with great interest.

The pioneers in medical social work have had to learn their trade through a long apprenticeship. Those now entering the field, however, can prepare themselves for it by special training, and there is a strong feeling on the part of executives in the existing departments that training should be encouraged and systemized to the fullest possible extent.

Under the pressure of this demand for training schools of social work have developed new courses, and one college, Smith, has created a new training school for the especial purpose of teaching medical and psychiatric social work. Training can now be had in Boston, New York, Northampton, Philadelphia, Indianapolis, and Chicago. The New York School of Social Work gives a two-year course. Teacher's College has a course for nurses. The Boston school gives a two-year course and a one-year course. The Smith Training School gives a course covering thirteen months, including two summer sessions, from July-August, and nine months of practice in hospitals. The Philadelphia School gives a one-year course. The Social Service Department of Indiana University gives undergraduate and graduate courses in Medical Social Work. The Chicago School of Civics is planning a course to start this year. Field work in hospitals is a part of the training in all the above schools.

Work is waiting for the classes that shall come from these schools. Much work needs doing and is not done for lack of workers. The field is full of opportunity; one who brings into it trained intelligence and energy is sure to make progress and may even add to the sum of human knowledge. Certainly the future of medical and psychiatric social work depends upon the coming procession of trained workers.

HEALTH HAZARDS IN CHEMICAL INDUSTRIES

The New York State Department of Labor has issued a special bulletin on "Health Hazards of the Chemical Industry" in New York State. This bulletin of 69 pages summarizes the results of a study of the following conditions: (1) The heating of factories with the fire hazards presented thereby; (2) Lighting of factories, and the location of switches, fuse plugs, and electric bells, particularly where inflammable liquids were used and the danger of explosion was present; (3) Tanks, particularly those in which there was the possibility of the generation of excessive pressure; (4) Hazards due to breaking up of raw materials; (5) Spontaneous combustion occurring in certain materials; (6) Industrial poisoning not reported to the Industrial Commission because they are not included in the list enumerated in Section 65 of the Labor Law; (7) Causes of explosions which occurred during the course of the investigation; (8) Lack of knowledge, by the men employed, of the character of the materials handled, as shown by the careless modes of handling both raw material and finished products; and, (9) General safe and unsafe practices.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

THE PERITONEUM. Vol. I, Structure and Function in Relation to the Principles of Abdominal Surgery. By Arthur E. Hertzler, M.D., F.A.C.S., surgeon to the Halstead Hospital, Halstead, Kas.; associate professor of surgery, University of Kansas; formerly professor of pathology, experimental surgery and gynecology, University Medical College, Kansas City, Mo. A contribution from the laboratory of the Halstead Hospital, and from the Department of Anatomy of the University of Illinois; and Vol. II, Diseases and Their Treatment.[1]

Hertzler's work on "The Peritoneum" comprises two volumes. In the first volume he discusses the structures and functions of the peritoneum, especially in relation to the principles of abdominal surgery. The chapter on the "Prevention of Adhesion" is very interesting and ought to be especially recommended to those surgeons who depend on posture, oil, or any of the other so called preventatives for adhesions to overcome that which they aggravate by neglecting the following simple rules, "to use the utmost of gentleness and care, to place the minimum of foreign bodies of all sorts, either temporary or permanent, within the abdominal cavity, and to cover every denuded surface as carefully as tho it were an unpardonable sin."

Volume two deals with the diseases of the peritoneum and their treatment. Under diseases of the peritoneum the author discusses tumors, tuberculosis, peritonitis in appendicitis, cholecystitis, gonorrhoeal peritonitis, etc., etc.

The many excellent illustrations by Mr. Tom Jones, the exhaustive bibliography, and the careful index, still further enhance the value of the work.

THE PROBLEM OF THE NERVOUS CHILD. By Elida Evans. Introduction by C. G. Jung, M.D., LL.D.[2]

This book is written for the purpose of aiding parents who, in the training and education of their children, have arrived at the point where the methods already used have proved inadequate. The author has succeeded in presenting the problems in an analytical manner calling attention to the many complexities of the child's physical and mental life. As to a solution to the many problems, not every reader will agree with all the suggestions made by the author. One who is at all acquainted with the subject knows that there is no one solution; that each problem requires a different answer, and that each child must be individualized. The author is too much under the influence of psycho-analysis and therefore sees matters too frequently from that point of view, attributing many simple phenomena in life to nothing else but sexual instinct.

In general the book is clearly written and should be read by parents, teachers, and physicians.

INJURIES TO THE HEAD AND NECK. By H. Lawson Whale, M.D., Camb., F.R.C.S., Eng. Capt. R.A.M.C. T.F.; Surgeon for the Ear, Throat and Nose to the London Temperance Hospital, and to the Hampstead General Hospital With a preface by Colonel Frederick F. Burghard, C.B., M.D., M.S., F.R.C.S.[3]

In this book the author describes battle wounds of the head and neck as he saw them and treated them at the Base Hospital at Sidcup, England. The author has not attempted to publish a text book, but has gathered an interesting group of cases covering the general type of head and neck injuries He has discussed at length the symptoms, signs, mode of treatment, and results. Injuries to the brain and eye are not included.

The book will be of interest, especially to the otorhinolaryngologist who during the war has been in close touch with oral and plastic surgery. R. B. B.

TEXT BOOK OF SURGICAL OPERATIONS. Illustrated by Clinical Observations for Physicians and Students. By Prof. Fedor Krause, Privy Medical Councilor, Directing Physician, Augusta Hospital, Berlin. In Association with Emil Heymann, M.D., Chief Physician, Augusta Hospital. Translated into English and edited for American readers by Albert Ehrenfried, A.B., M.D., F.A.C.S., assistant visiting surgeon, Boston City Hospital; surgeon Boston Consumptive's Hospital; assistant in surgery, Harvard Graduate School. In six volumes.[4]

The first two volumes of Krause, Heymann, Ehrenfried's six-volume text book of surgery have reached the reviewer. The entire arrangement is original. The reader realizes that he is receiving the advantage of the personal experience derived from the enormous practice of a surgeon of undisputed fame. The careful analytical presentation of the subject matter conveys the assurance that the chapters have not been compiled from other textbooks, but that the authors have pondered deeply over the matter, tried out several different theories and methods, and, because of their results, have finally decided on those published.

The aim of Dr. Krause was to present a treatise of operative surgery from a clinical aspect. For this reason each individual condition is exemplified by an actual case history. In these histories the important diagnostic factors are brought out.

The operative treatment is given in detail, the exact protocols having been dictated at the operating table. The various steps are well illustrated by means of actual photographs and sketches. Where it was possible to check up by means of post-mortem examination, the autopsy findings are recorded. The after-treatment and results are given.

The books are well written, well illustrated, well printed. The subject matter is the gratifying result of careful study. The work is sure to meet with the favor of the surgeon, the teacher of surgery, and the student.

Solvent with High Germicidal Action

ALTHOUGH Hyclorite (undiluted) has 7 to 8 times the hypochlorite strength of the ordinary Dakin's solution, clinical tests show that Hyclorite diluted to make a Dakin's solution is less irritating than the Dakin's solution commonly prepared from other agents, since its alkalinity is lower and of less irritating character.

Hyclorite is a solvent of necrosed tissue.

It is always ready. Just add water. No testing needed.

Prepared always to a definite hypochlorite strength (Na OCl 4.05%) and exceedingly low alkalinity.

Possesses remarkable stability and thus may be kept without loss of germicidal activity for long periods.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

Books of the Month

(Continued from Page 642)

THE CHILD IN HEALTH AND ILLNESS. By Carl G. Leo-Wolf, M.D.

The author of this book has departed from the customary style of writing books for mothers, in that he included not only information about the healthy child, but also information and suggestions about the sick child. On the whole, the author was successful in presenting a book to the young mother that supplies information and yet does not make a doctor out of her. Some illustrations are rather superfluous, as for instance the one "Filling a hot water bag," and the one "Pad over diaper." These illustrations add nothing to the book. Most of the illustrations, however, are clear and useful.

SIMPLIFIED INFANT FEEDING, with eighty illustrative cases. By Roger H. Dennett, B.S., M.D., associate professor of diseases of children, New York Post-Graduate Medical School, attending physician of the Children's Department, New York Post-Graduate Hospital.[6]

The book presents the subject of infant feeding in a clear manner. The word "simplified" in the title is possibly too strong a term. For years pediatricians have been trying to simplify infant feeding, some by hard and fast rules, others by short formulas. So far they have met with no success. One cannot learn infant feeding while standing on one foot, just as one cannot learn gynecology or obstetrics by simplified methods. The book deserves a place in American pediatric literature.

DISEASES OF THE CHEST AND THE PRINCIPLES OF PHYSICAL DIAGNOSIS. George William Norris, A.B., M.D., and Henry R. M. Landis, A.B., M.D. With a chapter on the Electrocardiograph in Heart Disease by Edward B Krumbhaar, Ph.D., M.D. Second Edition, Revised.[7]

Nothing but good can be said of the second edition of this book, which is an improvement over the first edition. It is well planned and well executed. Diseases of the chest are thoroughly and exhaustively covered and the book work itself is a model. The illustrations are particularly valuable, as almost all of them are specimens or records of actual cases. The cross-section method is used to a great extent, and this is always the most logical way of presenting pathological causes for changes in physical signs. The book cannot be recommended too highly.

SYMPTOMS IN THE DIAGNOSIS OF DISEASE. Hobart Amory Hare, M.D., B. Sc. Eighth Edition, Thoroughly Revised. Illustrated with 195 engravings and 9 plates.[8]

Here is another book in its eighth edition, a book which considers the disease from the standpoint of the patient's symptoms. It contains a well digested mass of clinical observation which certainly must be of considerable value to the practicing physician. One wonders, however, whether the method is a good teaching method for younger students of medicine who have not previously digested the study of disease from the standpoint of abnormal physiology. If the prime purpose of education is to teach men to think, then we doubt how much good is obtained from learning that "the headaches of indigestion are characterized by two important facts..... that they are often relieved or prevented by the use of a purgative, even if constipation has not been present." For we know that almost any type of inorganic headache may be relieved by a good purge. However, this philosophical objection does not detract from value of the book when placed in proper hands.

It's Easy to Overcome Many Disorders When Their Cause Is Recognized

PHYSICIANS now generally recognize that improperly-selected and badly-prepared food may predispose to Brights disease, diabetes, rheumatism, blood pressure changes, tuberculosis, rickets and cachetic conditions, neurasthenia, anemia, and all forms of indigestion, malnutrition and mal-assimilation.

In any of these disorders it is highly desirable to increase the digestibility of the food, and prevent pathological deviations in the isomeric transformation of the proteid molecule.

Food that is "slow fried,"—that is saturated with grease, lard and other fats that cannot stand high temperatures without burning—is an actual exciting cause of many abnormal conditions.

Mazola is capable of being heated to a temperature of 650° or more before burning. Meat, fish and other food fried in Mazola, have their surfaces seared over almost instantaneously. There is no loss of odor or flavor; and there is only a minimum of absorption of this oil form.

Patients troubled with flatulency, who suffer from gastric and abdominal distress after eating, usually improve when their food is prepared with Mazola, instead of animal fats or ordinary cooking compounds.

Mazola is a perfectly splendid salad oil, sweet and bland, and very readily assimilated in this form.

Order your patients to prepare their food with Mazola, Doctor, and note the rapid improvement in their condition.

CORN PRODUCTS REFINING COMPANY

HOME FOR INTEMPERATES BECOMES HOME FOR THE WORTHY

The Massachusetts Home and Hospital for Intemperate Women has become the Massachusetts Home for Needy, Worthy Women as a result of the workings of prohibition. The Institution was one of the oldest among Boston's charities. With the passing of liquor the need for its service rapidly decreased.

CURTAILS WELFARE WORK

It is reported in the press that the Youngstown Sheet and Tube Company, Youngstown, Ohio, has abandoned a large part of its welfare work conducted by the Industrial Relations Department. It is said that this action was determined upon because employees do not want and do not appreciate the assistance of the Welfare Department. During the past five years this Company has developed a comprehensive program, including Americanization work, visiting by skilled nurses, legal aid, hospital and medical service, and home building. It is announced that the employees' representation plan and the home building plans will be continued.

STUDY CAUSES OF LONGEVITY

A study of persons who have lived to be seventy years of age or more has been undertaken by Benzion Liber, M.D., D.P.H., 61 Hamilton Place, New York City, with the purpose of discovering the cause why their lives have been longer than that of the average man, and in the hope that conclusions may be reached which will help in the prolongation of the life of others. The collaboration of physicians, public health officers and social workers is desired in order to bring together a large number of observations. Those sufficiently interested in health conservation to give this matter some of their time whenever they meet an old man or an old woman will be supplied by Dr. Liber with copies of his questionnaire.

NEW HEALTH MOVEMENT

A new health movement, "The Woman's Foundation for Health," is being planned by the Y. W. C. A. and fourteen cooperating organizations. The plans provide for a central bureau and also health centers in six or eight sections of the country. These health centers will attempt to coordinate the educational, social, and recreational agencies of a community for constructive health work, especially in the promotion of mental and emotional health. "The average person by the term 'health'," says Dr. Hannah Morris, "generally means a study of mere physical health, but we realize now what a large part our thoughts and emotions play in our physical condition."

THE HIGH COST OF INFECTION

In the report of the Massachusetts Industrial Accident Board from July 1, 1918, to June 30, 1919, the total number of accidents reported was 178,045. The cases of infection from these injuries of this number were 5,178; 19 cases were fatal; 34 of the cases resulted in permanent partial disability; one in every 13 non-fatal cases became infected. The total amount paid out for medical expense and compensation to injured employees for the year ending June 30, 1919, was $5,219,760.24. It is estimated that 7 7/10 per cent of this expense, or $401,921.57, was due to infection, an unanswerable argument that greater effort must be made to diminish the number of infections.

Perfect Relaxation, Rest, Comfort—and Sleep

The production of Simmons Beds begins on the common sense principle that a bed is first of all made to sleep in .

EVERYBODY knows that sound sleep means sleep of complete relaxation and repose, yet such a condition cannot be brought about unless one's *bed* invites it.

The choice of a bed, spring and mattress is therefore important—*very* important, if the sleep we get is to be of that refreshing, invigorating character so necessary to good health and personal efficiency.

Few people get enough sleep. Many even begrudge the time the right kind of sleep requires. Others get their full night's sleep but are not *rested* when morning comes.

Still others are not benefited by the sleep they get because their sleep is disturbed by the mechanical squeaks and rattles of their bed, its springs, or the hard, unyielding character of its mattress.

Nobody can really sleep deeply and be fully benefited by their sleep unless he or she is completely relaxed—unless the bed, spring and mattress are so comfortable as to invite repose and sleep.

Simmons Beds, Springs and Mattresses, "Built for Sleep" cost no more than perfect merchandise of this character ought to cost; no more than anybody who values comfort and health is prepared and willing to pay.

Noiseless, supremely comfortable and altogether serviceable—they are always to be distinguished by the Simmons Mark—an unfailing assurance of quality, sanitation, comfort and service.

Special Data and descriptive booklets of Simmons Sleeping equipment for Hospitals, Schools and Recreation Camps, will be mailed upon request

REPORT OF INDUSTRIAL PHYSICIANS AND SURGEONS

The Proceedings of the American Association of Industrial Physicians and Surgeons for the convention held in Atlantic City June, 1919, have recently appeared. This volume of 127 pages is a valuable contribution to the growing literature on industrial medicine and surgery. It contains not only the papers presented at the meeting, but all of the discussions which ensued.

GUARD WORKMEN FROM BUZZ SAWS

The Massachusetts State Department of Labor and Industry has formulated regulations providing that circular rip saws shall be guarded by spreaders located in the rear of the saw and under the table. Similar precautions are to be taken with other kinds of saws, these regulations being designed to lessen the hazards connected with the wood working occupation.

INSTITUTE FOR INDUSTRIAL NURSES

AN institute of industrial nursing is to be held under the auspices of the Visiting Nurse Association, 35 Elm Street, New Haven, Conn., September 20-23, 1920.

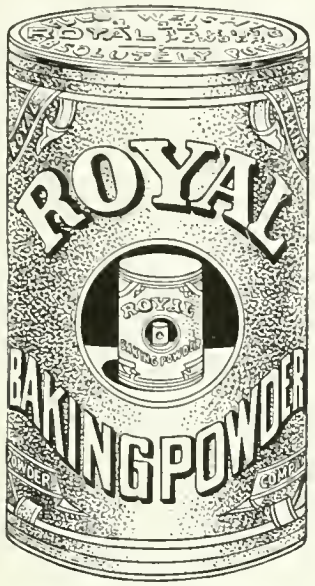
This institute offers a brief and intensive training in the problems of industrial nursing, organization, industrial hygiene, industrial management, and social reconstruction as these problems are related to the practical work of the nurse in industry. A grasp of these broader relationships which find no place in the ordinary training of the graduate nurse is essential for the fullest success, and knowledge is progressing so rapidly that even the most experienced industrial nurse can profit by contact with leading authorities on public health and industrial relations for the discussion of the latest advances in these fields.

Efficient factory management is recognizing more fully, month by month, the importance of special training in this field of work. The industrial nurse who can carry on the routine work of the plant hospital efficiently and can also assist in adjusting family problems and keeping the employee and his family physically fit and happy, is an asset not only to the industry, but to the community at large. The Institute is designed for graduate registered nurses who are engaged in, or desire to be engaged in industrial nursing.

The registration fee will be five dollars, payable at the time of registration. No application for registration will be received after September 12. The office of the Visiting Nurse Association will secure rooms through the Young Women's Christian Association for nurses if they write for reservation at least two weeks before the institute opens.

New Haven is one hour and forty-five minutes ride from New York City, located on Long Island Sound. Facilities for sea bathing, boating, tennis, and other sports, and pleasant walks, are available to students. Miss Carin H. Degermark, director of recreation for women. Community Service, will have charge of the recreational program.

Excursions to industrial plants will be in charge of Christine C. Gardener of the United States Rubber Company. Topics on the program include public health nursing, industrial hygiene, social problems and case work, hospital organization and record keeping, industrial diseases, industrial relations, industrial psychology, nutrition, and state health programs.



A Can of

ROYAL
Baking Powder

contains no doubts as to quality, purity or wholesomeness.

Royal Baking Powder is made from cream of tartar, derived from grapes, and has no equal for making healthful, appetizing muffins, biscuits, cake and pastry.

RAILWAY SURGEONS TO MEET

The thirtieth annual session of the New York and New England Association of Railway Surgeons will be held at the Hotel McAlpin, New York City, October 19, under the presidency of Dr. William B. Coley. Dr. George W. Crile, Cleveland, will deliver the address on surgery.

INTERNATIONAL MEDICAL CONGRESS

The Fifth International Medical Congress convened in Paris July 19 and was welcomed by Premier Millerand. This conference devoted a large part of its time to the progress made in the practice of medicine and surgery since the beginning of the war. More than twenty American physicians and surgeons attended the conference.

NEW MEDICAL SERVICE BULLETIN

The Liberty Mutual Insurance Company of Boston has begun the publication of a series of medical service bulletins. The August issue contains articles on the "Treatment of Burns," "A Step in the Radical Cure of Inguinal Hernia," "A Comparison of Laboratory Tests of the Effectiveness of Aristol and Ferstade Powder," and "Punctured Wounds."

OCCUPATIONAL BUREAU FOR NURSES

The National Organization for Public Health Nursing with headquarters at 156 Fifth Avenue, New York City, and branch office at 116 S. Michigan Avenue, Chicago, is conducting an informal occupational bureau. Nurses desiring new positions are earnestly requested to communicate with the Organization. Associations or firms needing nurses are also asked to write or visit the N.O.P.H.N. No charge is made for the service.

CONFERENCE ON VENEREAL DISEASES

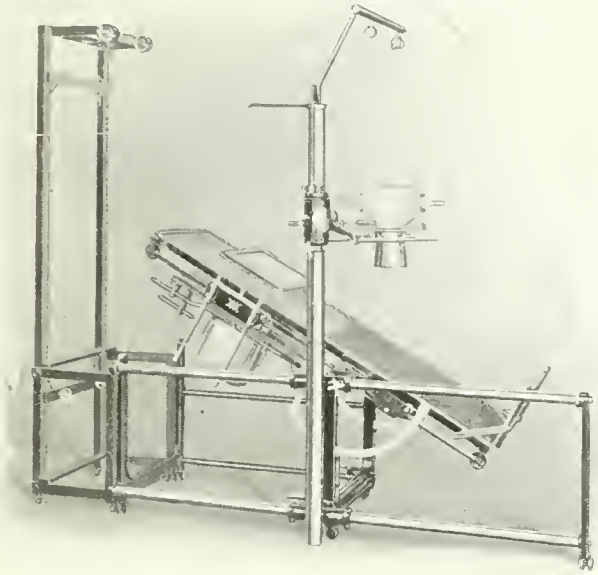
A Pan-American conference on the control of venereal diseases will be held in Washington, probably in December, under the auspices of the American Red Cross, the United States Public Health Service, the United States Interdepartmental Social Hygiene Board, and the American Social Hygiene Association. The work of the conference will deal with three different groups of problems in the control of venereal diseases, namely, the purely scientific, the administrative, and those which have particular public interest.

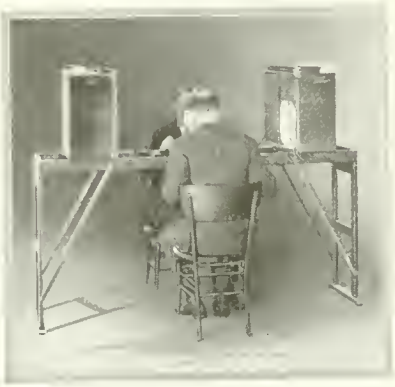
COST OF LIVING

The latest figures on the cost of living of working families issued by the United States Department of Labor Statistics for the principal cities of the country show that there has been an increase since December, 1915, of 114 per cent in Baltimore, 110 per cent in Boston, 114 per cent in Chicago, 136 per cent in Detroit, 119 per cent in New York, 122 per cent in Norfolk, 113 per cent in Philadelphia, 110 per cent in Seattle. The cost of food alone has increased 110 per cent in Baltimore, 105 per cent in Boston, 120 per cent in Chicago, 132 per cent in Detroit, 105 per cent in New York, 107 per cent in Norfolk, 101 per cent in Philadelphia, 102 per cent in Seattle. The figures show that the cost of food alone took 42 per cent of income in Baltimore, 44 per cent in Boston, 37 per cent in Chicago, 35 per cent in Detroit, 42 per cent in New York, 34 per cent in Norfolk, 40 per cent in Philadelphia, 33 per cent in Seattle.

YOUR X-RAY EQUIPMENT

is incomplete without the **Meyer Multoscope,** the only apparatus with self-contained overhead and aerial switch and many other exclusive features.





The Duplex Stereoscope, the only stereoscope allowing two observers to view at the same time, each having independent control over vertical, angular and focal adjustment.

The only stereoscope for instruction.

One-Cent Hearty Breakfasts

Quaker Oats costs one cent per large dish. It forms almost the ideal food in balance and completeness.

One chop would cost about 12 times as much. And each egg costs some 4 or 5 times a dish of Quaker Oats.

Quaker Oats, in calory value, is twice as rich as round steak. Yet it costs about one-tenth what meat and egg foods cost.

Folks should remember in these high-cost days that the greatest food that grows still costs but little.

At this writing, this is what some necessary foods cost on the calory basis.

Cost per 1,000 calories	
Quaker Oats	5½c
Average Meats	45c
Hen's Eggs	60c
Chicken up to	$1.66

Quaker Oats

Extra-flavory flakes without extra price. They are flaked from queen grains only—just the rich, plump, flavory oats. We get but ten pounds from a bushel.

The Quaker Oats Company
Chicago

TRAINING NUTRITION WORKERS

An institute for the training of nutrition workers under the direction of Dr. William R. P. Emerson, under the auspices of the Elizabeth McCormick Memorial Fund, Chicago, has just been held. The class of thirty included dietitian school nurses, four physicians, two members of school boards, and various executives of child welfare organizations. Seven states were represented in the group. The work consisted in actual participation in dietitian work and included lectures, conferences, class discussions and reports.

INFANT MORTALITY CUT DOWN

The infant mortality rates for the twelve largest cities in the Birth Registration Area in the United States is compared in a recent bulletin for the five year period just past with a highly favorable showing for 1919. Seven of these cities showed decreases of from 8.5 to 23.4 per cent, while the highest increase was 3.6 per cent.

In New York City the death rate of infants under one year of age decreased 11 per cent, compared with 1918, and was 18 per cent below the 1915 figures.

In Philadelphia the decrease was 33 per cent from the previous year; in Cleveland 3 per cent, Baltimore 51 per cent, Detroit 4, Pittsburgh 25, Buffalo 11, Milwaukee 5, Washington 37, Cincinnati 16, and Minneapolis 8 per cent.

For the entire country Lackawanna, N. Y., showed the largest improvement, the decrease in infant mortality being 74 per thousand births.

HEALTH EDUCATION IN CHINA

The Joint Council on Health Education has as its purpose the task of inducing China to set her hygienic house in order. Lectures, lantern exhibitions, ingenious working models, and other means are used, says the *China Medical Journal*, to teach the Chinese people the elements of sanitation.

As elsewhere, the best results are attained in the schools among the children before opinions and habits are fixed. Traditions and superstitions need to be undermined. The difficulties of controlling epidemics are greatly increased when disease is generally believed to be a malignant demon which they must propitiate and fear to oppose. The willingness of people and officials to cooperate, so essential to a scientific campaign, depends upon an educational campaign directed against the superstitions concerning disease which prevail all over China.

NURSES WIN HIGHEST NURSING HONOR

Six American women, all of whom saw service in the World War, have just been awarded the Florence Nightingale Medal, the highest decoration of the whole nursing world. The distinction, which is bestowed by the International Committee of the Red Cross, Geneva, may be awarded only to one nurse in any nation, annually; thus these six women represent America's nursing roll of honor since the outbreak of the war in 1914. The terms under which the decoration was created in 1912 also provide that it be granted "only to trained nurses who may have especially distinguished themselves by great and exceptional devotion to the sick and wounded in peace or war."

These nurses, all of whom served with the American Red Cross, are Miss Helen Scott Hay, of Washington, D. C.; Miss Florence Merriam Johnson, of New York City; Miss Martha M. Russell, of Boulder, Colo.; Miss Linda K. Meirs, of Boston; Miss Alma E. Foerster, of Chicago; and Miss Mary E. Gladwin, of New York City.

Ariston Baking Powders

There are two kinds of good baking powder—Cream of Tartar and Pure Phosphate. Each is a perfect leavening agent, and we make both in highest possible quality.

Pure Phosphate is a real food, of value in the vital organism and in the building of bone structure. This food value—the leavening qualities being the same—justifies our favoring, as we do, the Pure Phosphate Baking Powder, which also costs less.

Making both kinds and having no prejudice either way, our preference for the Pure Phosphate powder may be accepted as impartial and dependable. Equally impartial comparative tests have convinced many users, who no longer pay the higher price for the lower food value of Cream of Tartar Powders.

CHLORIN FOR VACATIONISTS

The Department of Health of the City of Chicago offered to all persons departing on vacation this year to furnish a small bottle of chlorin tablets to take with them for the purification of water in cottage or camp. The Health Commissioner explained that typhoid fever in Chicago was brought in from other points. Chicago has had one of the lowest typhoid fever rates of any large city in the world.

SHORTAGE OF DENTISTS IN ENGLAND

The inspection of conservative dentistry to the masses in England has led to a relative increase in the demand for dentists. Even if the dentists now available devoted their whole time to school work, they could not cope with the needs of the 5,750,000 school children while neglecting the rest of the population, and unfortunately, according to *The Lancet* of June 5, 1920, the British need for good dentistry, preventive and curative, has been allowed by popular ignorance and slackness to become a national reproach. The need of students of dentistry is urged, as well as the importance of the dentists as a valuable ally in the cause of preventive medicine.

CHILD WELFARE IN ONTARIO

The Provincial Board of Health of Ontario has undertaken a program for maternal and child welfare work of a highly progressive nature, according to the July issue of the *Public Health Journal*. Forty thousand dollars has been appropriated by the government for the purpose of establishing in each health district a public health nurse whose purpose it will be to carry on maternal and child welfare work as well as general public health nursing, under the supervision of a district nurse. Local community health centers will be organized and every effort possible will be made to stimulate local interest in health matters through traveling health exhibits and general educational material.

The general direction of the work will be in the hands of Miss Mary Power, with Miss Knox as assistant director. A supervisor, a pediatrician, and an expert dietitian will be added to the staff.

CLEVELAND ACADEMY ISSUES BULLETIN

The Academy of Medicine of Cleveland has undertaken the publication of a bulletin, the first number of which appeared in July, under the editorship of Guy M. Wells. The purpose of the publication is apparently not medical, but economic.

The first issue is devoted principally to attacks upon health insurance. As a sample of the kind of policy which apparently is to be pursued, we quote the following:

"The medical profession in dealing with the problem of compulsory state health insurance must adopt an aggressive constructive policy. To sit by and give free rein to the un-American Socialists, the anti-labor Bolshevists, and the impractical social uplifters (who have taken their thirty pieces of silver from the industrial interests of Germany and Great Britain), until they have fastened this Bismarckian scheme on Ohio, and then try to lock the door after the horse has been stolen, will be useless as it will be ludicrous."

Judicious comment is impossible upon such statements coming from an official bulletin of a reputable Academy of Medicine.

MALNUTRITION

The little Sutton girl was so weak it was thought she could not be raised. Immediately she was put on VIROL she began to mend. The larger photograph shows the remarkable improvement made on VIROL. These photographs and details were furnished by the attending physician.

Virol is a dependable nutrient and reconstructive in all wasting conditions, in tuberculosis, anaemia, gastric ulcer, rickets, scurvy and all strumous conditions.

Virol is rich in the food accessory substances known as vitamines, and especially in the fat soluble vitamine. Recent feeding experiments have shown the important part played by these vitamines not only in development and growth and in the prevention of rickets, but also in raising the power of resistance to diseases of bacterial origin.

Virol is composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars, 50c, $1.00 and $2.00.

Virol

Used in more than 2000 hospitals, sanatoria, and infant clinics in Great Britain

Liberal samples of VIROL and interesting literature will be mailed to physicians on request.

PLAGUE EXPERT URGES WAR ON RATS

Dr. Victor G. Heiser gave a lecture before the Post-Graduate Medical School and Hospital in New York August 9, in which he urged that steps be taken to prevent the entrance of the bubonic plague into this country. Declaring that the plague is almost exclusively a rat-borne disease, he urged that thorough fumigation of ships be made upon entrance to the ports with sulphur or gas from cyanide of potassium. "Building laws should be amended," he declared, "so as to require rat-proof construction of buildings and docks." On the economic side, Dr. Heiser pointed out the fact that the destruction of rats, aside from eliminating the danger from the plague, would save the United States over $200,000,000 a year.

Dr. Heiser is one of the best known plague experts, having had more than twenty years' experience in fighting the plague in different parts of the world. He was Director of Health in the Philippines for ten years, where he gained a wide reputation for the measures adopted in fighting the plague in those islands. He has just recently returned from Central and South America, where he has been studying the subject for the Rockefeller Foundation.

SHORTAGE OF NURSES

The grave shortage of nurses has caused a widespread campaign by hospitals, physicians and social workers to induce young women to enter the profession. Among those who are taking an active hand in the campaign is Bird S. Coler, Commissioner of Public Welfare in New York, and his co-workers in the Department.

"This scarcity of nurses," said Miss Agnes S. Ward, General Superintendent of Nurses in the Department, "is due primarily to changes brought about by the World War, which had the effect of bringing into close relationship the people of many nations, who were quick to recognize and appreciate the value of the nurse's services. Today they are feeling the need of nurses and they are beseeching us to send them nurses, that they may establish schools and institutions.

"As a result of the war the nurse's sphere of usefulness has increased tremendously. Public health centers are being established all over the country, and some 50,000 nurses are needed for this work alone. There are between twenty and thirty distinct lines of work in which nurses may engage.

"Big business has not been slow in recognizing the value of the trained nurse, and it is estimated that two-thirds of our factories, insurance companies, large stores and corporations employ one or more nurses. They have found them indispensable in emergencies."

"The big thing today," Miss Ward said, "is the desire to prevent illness, and this work is bearing fruitful results in schools, institutions, and homes where nurses are instructing young men and women and mothers in hygiene and in correct living. It means better living conditions, better citizens, and a more healthy and a more useful race.

"Many misconceptions exist concerning nursing as a career, and undoubtedly some of them have prevented young women from taking it up as a profession. Nurses have been pictured as overworked creatures with little time to themselves, leading more or less of a dog's life. Some of the harsh things which were said about it might have been true years ago, when as a profession it was in its early evolutionary stages, but certainly today nurses work no harder and enjoy the same freedom and independence as women in other vocations."

DIET IN INFANTILE DIARRHEA

Mead's Dextri-Maltose Nos. 1 and 2 are used by many pediatricians as constituents of feeding formulas presented in certain forms of diarrhea and for diet while recovering from diarrhea and for children predisposed to diarrhea.

Three Forms

No. 1. With 2% Sodium Chloride.

No. 2. Unsalted.

No. 3. Same as No. 2, plus Potassium Carbonate 2%.

An interesting discussion of corrective diet reflecting the most recent research in this field will be sent you for the asking, together with sample of Mead's Dextri-Maltose and full information regarding its constituents and indicated uses. If you are bringing babies through the trying "first year," write for it.

The Mead Johnson Policy

Mead's Dextri-Maltose is advertised only to the Medical Profession. No feeding directions accompany trade packages. Information regarding its use reaches the mother only by written instructions from her doctor on his own private prescription blank.

MEAD JOHNSON & CO., 303 St. Joseph Ave., Evansville, Ind.

Physical Conditioning

So many patients, especially women, lack the initiative to follow general advice regarding exercises, dietary, and personal hygiene. Physicians acquainted with my work are constantly referring these cases to me for physical and mental "conditioning."

A woman can often inspire her sex *to be* and *to do* and *hold her to this inspiration* by regular correspondence as men cannot.

Every pupil's requirements are studied individually, and each is directed according to her needs and her strength.

This cooperative work with the medical profession is giving results highly gratifying to both physicians and patients.

I shall be glad to assist you with patients who need conditioning through exercise, diet, breathing, correct poise, relaxation, reduction of flesh, or building of flesh.

G. H. SHERMAN, M.D.
Detroit, Mich. U.S.A.

"Sherman's Vaccines are dependable Antigens."

HOUSING CRISIS IN NEW YORK

Approximately $560,000,000 must be invested in the construction of apartments in New York City to overcome its present housing shortage, in the opinion of the Mayor's Housing Conference Committee, called to help solve the housing crisis. The conference brought together representatives of the insurance companies and banks for the purpose of securing pledges of loans upon housing projects. So critical has the situation become that the Committee has announced that it will ask the State Legislature and the Board of Estimate to stop construction on buildings considered non-essential, including office buildings. Proposals have also been made to exempt new buildings from taxation. In the month of July permits were granted in New York for 115 garages and one apartment.

POVERTY NOT SOLE CAUSE OF MALNUTRITION

In an address before the Tuberculosis Association of Rochester, N. Y., Dr. William R. P. Emerson, of Boston, declared that investigations made in Boston, New York, Chicago and other large cities show that the physical unfitness of children is not solely the result of poverty, heredity, or some obscure disease, but is due to physical deficiencies, lack of home control, over-fatigue, improper food habits and improper health habits. Dr. Emerson declared himself in favor of school lunches at cost, or below cost to those who cannot pay, but he did not believe that the problem of physical unfitness of children could be solved by the provision of free lunches. He advocated the organization of children into nutrition classes in which groups of children meet once a week to be weighed and to have their health progress checked up by a nutrition expert who will give them a thorough education in health principles.

ADEQUATE ISOLATION HOSPITALS

Many factors need to be considered, says the *Lancet* of March 20, 1920, in arriving at the needs of a given community in isolation hospital accommodation, the most important of which are: the character of the district, whether urban or rural; the rate of increase of population; the housing and habits of a people; and the amount of intercourse with other places from which infectious disease may be introduced. Hospital accommodation should be provided for cases of scarlet fever, diphtheria, enteric fever, and cerebrospinal fever. For these four diseases one bed for every thousand inhabitants will not be excessive, but it will not provide for epidemic conditions.

To isolate measles or whooping-cough many more beds than this estimate will be required. If pulmonary tuberculosis is included, the needs of each district will require a separate estimate, taking account of all factors. The cost incurred in isolating small-pox may be regarded as the price the public has to pay for what is known as conscientious objection to vaccination. The site of a small-pox isolation hospital should always be sufficiently large to admit of rapid extension in case of necessity.

STUDY HEALTH SERVICE IN BRAZIL

A commission has been granted Dr. A. Neiva, chief of the Public Health Service of the State of St. Paulo, Brazil, for the study of the organization of the Public Health Service in Japan and in the United States, and also of the prophylaxis of leprosy in Norway, the Philippines and Hawaii.

MODERN MEDICINE

A Monthly Magazine of Medical & Health Progress for Physicians & for Others Interested in Administrative, Industrial & Social Health Problems

Editors, ALEXANDER LAMBERT, M. D., S. S. GOLDWATER, M. D., *and* JOHN A. LAPP, LL.D.
Managing Editor, JOHN A. LAPP
Editorial and Business Offices, 22-24 EAST ONTARIO STREET, *Chicago*

Volume 2 OCTOBER 1920 Number 10

HEALTH INTERPRETATION

THE new organization of medical service along the lines indicated by the development of the past two years points clearly toward group practice, at least for the purpose of consultative medical service, and toward making the existing hospitals and clinics more and more the center of the medical life of the areas in which they are located. The attention that has been paid during the past few years to maternal and infant welfare, to the medical supervision of schools, and especially to the percentage of remediable defects exhibited by the adult manhood of the United States in the physical examinations made during the period of the war, all go to show medical care to be needed by a large proportion of our population who are not getting it. The call for an extension of service is apparent at present and will become more urgent as an enlightened public opinion senses the need and demands early measures of prevention instead of corrections for the end results of disease.

A statement of the need of bringing universal service to people would fall short of its purpose if it did not include a study of the agencies now in the field, for out of the more effective organization of present agencies may we hope to bring the service of the physicians to all who are in need of it, to provide diagnostic facilities where they are inadequate or lacking, and to furnish the intermediary social service to make curative and preventive measures effectual. To what extent are we organized to meet the exigencies of the situation? Will a mere extension of present agencies cover the field? Is there wasteful duplication of effort? On what basis can our organizations get together for more effective team work? Some of these questions will be answered in a series of articles appearing in successive issues of MODERN MEDICINE on the more important national agencies for medical service and relief. The first of the series, in the September issue, presented the work of the Child Health Organization, over the signature of L. Emmett Holt, M.D. On another page of this issue appears the story of "A League for Health," by Canby Dunn, of the League of Red Cross Societies, Geneva Switzerland. The enlarged program of the National Tuberculosis Association will be presented by Philip P. Jacobs, assistant secretary of the Association. Future issues will contain papers by E. A. Peterson, director of the American Red Cross, on what this organization is and what it does; by J. Middleton Martin, county medical officer of health, Gloucester, Eng., on the Gloucestershire scheme for the extension of medical services; by Ella Phillips Crandall on National Organization for Public Health Nursing. Later papers will follow on the prevention and control of cancer, on the correction of postural defects, and on other coordinated efforts both under way and projected, all significant of the present trend toward a better organization of the social machinery for relief. S. P. M.

ABDICATING MEDICAL LEADERSHIP

THE attention of the scientific leaders of medicine should be called to a condition which is prevailing to an increased extent in some parts of the country: namely, the abdication of leadership in public matters into the hands of men who do not properly uphold the high ideals and the dignity of the medical profession. It is altogether too common to find the physicians represented by

spokesmen who are violent in their attacks upon their opponents in matters wherein their opponents are as likely to be actuated by high motives as is the medical profession itself. To read some of the attacks upon the advocates of health insurance by self-appointed leaders of the medical profession tries the patience of any fair-minded person.

In a recent editorial in the *Survey* on the subject of "Doctors and Health Insurance" appears the following statement which should be weighed by the real leaders of the medical profession: "That part of the medical profession which is hostile to health insurance is very badly served by some of its spokesmen," says the editorial.

"Physicians are proverbially gentlemen. They are public spirited. They are the first servants of humanity, responsible to their conscience and amenable to the high ethics of their profession. They are law-abiding and respecting. They do not work for filthy lucre, but for the satisfaction of preserving life and safeguarding health. They are the very salt of the earth.

"But in the new counterfeit presentment which their self-appointed artists have drawn for us, they are none of these things. They have gone into politics, not to secure pure milk, better housing, or an efficient health department, as it is their noble tradition to have done so often; but to defeat excellent members of the legislature for having voted for health insurance. They are after power, not in order to serve, but in order to protect their pocketbooks. Like Britons, they never, never will be slaves.

"If the state enacts laws providing for the distribution of the costs of sickness—although this is an economic and not a medical question at all —they will refuse to practise medicine. They do not have to care for the sick—no, sir! they will go into business or practise law. Better still, they will go into politics now and defeat every candidate even of their own party who has anything whatever to do with extending the insurance principle to sickness.

"They don't believe in workmen's compensation either. They were fooled that time, but never again! What does it matter that industry is creating a sickness disability every day for which it does not provide financially? Not workingmen, but business men and investors are the better paying clients. Therefore, let us become the tools of exploiting employers; and try to persuade workingmen that they are better off in a chaotic, anarchistic, individualistic practice of medicine than in one which is organized, socialized, and modernized. Let us insinuate that these pestiferous intermeddlers have a sinister motive. They are probably chiropractors or osteopaths in disguise. At any rate there is a 'nigger in the wood pile' somewhere.

"This is not our caricature. It is that which the medical profession are allowing physicians presumably in good standing not a thousand miles from the New York Academy of Medicine to draw of present-day physicians."

The appeal of this editorial is for straighter thinking and better leadership than that which evidences itself at public hearings on this question and others when the interests of the medical profession are at stake. It is a plea for the doctors to condemn "obstructive, dog-in-the-manger, pettifogging tactics."

Any one may be opposed to health insurance for a variety of reasons and any one may favor health insurance for a variety of reasons. The attempt of the self-appointed spokesmen to label everything with which they disagree as un-American reacts against real medical leadership. Public issues must in the long run be settled by reason and not by violent talk.

PHYSICIANS CONFER WITH SAFETY COUNCIL

IT IS a good omen when a body of such live and competent men, all leaders in their several fields, come together in conference, as was the case in the meeting which convened September 27 to October 1, in Milwaukee.

The papers presented were such as to impress everyone of the desire of these men to understand the psychology of the times, to find through the agencies of safety and medical service those contacts which make for mutual good feeling, and through such service to break down the barriers of distrust which too often exist between the management and the men.

Especially pertinent in this connection were the addresses of the representatives of the American Association of Industrial Physicians. The medical service of industry is not to be isolated from the preventive health work of the community, of which it is a vital part and from which it differs only in a few added special problems. Industrial surgery is a specialty as important as any other, and calls for the utmost skill and judgment. The toxicology of industry is an urgent and alluring field, and one calling for research workers. Medicine in industry requires right-minded physicians of executive ability, men of skill and fine social qualities, and it is largely through the leadership of such men that better relations are to be developed and energetic, successful, and growing communities made to replace the apathy, ill health, and discontent which obtain in many industrial communities today.

HEADS AMERICAN PUBLIC HEALTH ASSOCIATION

THE newly elected president of the American Public Health Association, Mazyck Porcher Ravenel, M.D., brings to that office the technic of a skilled bacteriologist, the acumen of a man of letters, and the ripe judgment of long professional experience. He was born in Pendleton, S. C. He graduated from the University of the South in 1881, receiving his degree of Doctor of Medicine in 1884. This was followed by study in the Pasteur Institute of Paris, the Hygienic Institute of the University of Halle, and the Maragliano Institute of Genoa, Italy. He was for some years chief of laboratories of the Henry Phipps Institute, and later held the chair of bacteriology at Wisconsin. He was director of the State Hygienic Laboratory of Wisconsin from 1908 to 1914. His work at the Henry Phipps Institute was for some time directed toward the study, treatment and prevention of tuberculosis. He is now connected with the University of Missouri. His research work has been varied and his published work covers many bacteriological subjects, notably tuberculosis and rabies.

Mazyck Porcher Ravenel, M.D., newly elected president of the American Public Health Association.

AMERICAN PUBLIC HEALTH ASSOCIATION

NEITHER the extreme western location of the conference meeting place, nor the recent advance in railroad transportation had an unfavorable effect on the attendance of the 49th annual conference of the American Public Health Association held in San Francisco, September 13 to 17. The smaller number of representatives from the Atlantic seaboard was more than made up by the large number of public health nurses, social workers and other visitors from the Pacific coast who attended the various sessions.

Dr. W. S. Rankin's presidential address, delivered before one of the largest gatherings ever assembled at the Association's meetings, emphasized very forcefully the need for a national popular health journal, also the importance of bringing about an early coordination of national health agencies both private and official. While at a previous meeting Dr. Vincent of the Rockefeller Foundation referred to the fifty-seven varieties of health organizations, Dr. Rankin stated that there are almost as many health agencies as there were causes of death.

Perhaps the most exhaustive discussion of the whole conference were the splendid and masterly addresses on the relative function of official and non-official health agencies as presented by Dr. Haven Emerson from the viewpoint of the official agency, and Dr. Charles J. Hatfield from that of the non-official agency. The marked similarity of opinion expressed by Dr. Emerson and Dr. Hatfield is very significant, both emphasizing the need for coordination of private health activities, at the same time fully appreciating the value of these voluntary agencies in health research, education, and demonstration. One important point brought out in this discussion was that the work of the private health agency, to be most effective, must be handled separately from that of the official health department, though of course in close cooperation with the latter body.

State and local health officers were particularly interested in the symposium on Bubonic Plague, which included a historical outline of the disease and methods for its detection, diagnosis, and control. The special sections and joint meetings were full of live, helpful papers and the standing and special committee reports were well received. Symposiums on food factory sanitation, narcotic drug control, and infant mortality were well attended. Public health nurses found special interest in the child hygiene and social sections.

PURPOSES OF THE LEAGUE FOR HEALTH*

By CANBY DUNN, Department of Medical Information, the League of Red Cross Societies, Geneva, Switzerland

MAN does not die. He kills himself. This maxim is unfortunately almost as true today as is was when it was voiced by Seneca nearly two thousand years ago. In every country there is an enormous amount of disease and misery which could be prevented or greatly reduced by proper hygienic measures; and in some countries disease, following upon the footsteps of war, has reached such proportions that it constitutes a direct menace to the health and future well-being of the whole world.

Resistance is Encountered

Public health authorities have long been cognizant of this condition. Their problem has been to get the people, themselves, interested; and sometimes they have wondered whether the statement of a brilliantly cynical scholar, "The capacity of the human mind for resisting the introduction of useful knowledge is beyond belief," might not be literally true.

Yet today there is such an interest in public health as there seldom, if ever, has been before.

It took the war, throwing down man's structure of organized peaceful life as though it were a house of cards, maiming and destroying the fittest of the world's youth, and piling up a burden of debt and reconstruction for future generations, thoroughly to awaken mankind to the size of the handicap, in the shape of preventable disease, under which it had been laboring.

As the war ended and civilization, so to speak, set up and began to take stock of the wreckage, it saw clearly that in order to carry on it would need the efforts of every available person. It could never replace the millions of lives lost in the conflict, but it wondered whether it could not in some way make up for them by saving the millions of lives which disease in the ordinary course of events would surely claim. England, for instance, lost through sickness in 1916 the equivalent of 243,000 years of productive work. Could not this formidable figure be greatly lowered? Could not the United States do something about the 630,000 annual deaths from diseases regarded as preventable, and about its estimated annual wage loss from sickness of $500,000,000? Could not countries less well equipped to deal with disease—and which consequently would show, if statistics could be obtained, an even more impressive picture—be aided?

INTERNATIONAL ASPECTS OF PUBLIC HEALTH

As the activities of the several agencies for the improvement of public health conditions, both local and general, extend, it is more and more apparent that the field of one cannot be definitely delimited from that of another and some working basis of common interest becomes an ultimate necessity.

Disease itself does not respect political boundaries and if health work is to evolve more than temporary or palliative effort, the unhygienic centers which radiate disease must be searched out everywhere, and their noisome conditions changed.

The leading medical men of France, Great Britain, Italy, Japan, and the United States thought that all of these questions could be answered affirmatively. There were already in existence in many nations Red Cross organizations which had done yeoman work during the war in attempting to preserve life when the whole bent of the world seemed to be toward its destruction: they, too, felt that it was time to inaugurate a concerted attack on disease.

Accordingly, on April 1, 1919, on the invitation of the Committee of Red Cross Societies, a medical conference, numbering among its delegates some of the most distinguished medical men of the world, met at Cannes, France, and organized the League of Red Cross Societies.

Plan Basic Medical Program

This League's work for health is carried out along three broad lines: the stimulation of national Red Cross Societies; the direct collection and dissemination of health information; and the provision of a means of coordinating relief work undertaken on an international scale.

The Cannes Conference promulgated thirteen resolutions, the realization of which should be the basic medical program of the League of Red Cross Societies. These comprised a scheme of child welfare work; an endorsement of public health legislation and administration; the standardization of vital statistics; scientific investigation in hygiene and sanitary fields; the establishment of public health laboratories; and the development of pub-

*The second of a series of articles on National Health Organizations prepared for the pages of Modern Medicine.

lic health nursing. The prevention and control of tuberculosis, of malaria and of venereal diseases was outlined, as well as were plans for educational propaganda, town and city planning, the establishment of health centers, and the training of the children in hygiene. An attack on the typhus epidemic in Poland was recommended as an emergency measure.

It has been slightly over a year since the above program was laid down, and a barely twelve-month since the headquarters of the League of Red Cross Societies was established at Geneva. In that period thirty-one national Red Cross Societies have affiliated themselves with the League; the foundations for carrying out the League's plans have been solidly laid, both as regards personnel and definite outlines of work to be pursued; and several constructive measures have already been undertaken.

A medical commission was formed and sent to Poland on August 14, 1919, and a month later it rendered its report. This finding demonstrated so graphically the great extent of Poland's needs that Sir David Henderson, director general of the League of Red Cross Societies, pointed out that the situation in Poland seemed to demand governmental action on a scale on which neither the League nor national Red Cross societies were able to proceed. Not only in Poland proper was there need for assistance in the fight against the infectious diseases of which typhus headed the list; it was essential that some means be devised of checking the continued introduction of disease by refugees crossing the eastern frontier.

The report of the investigating commission was presented to the League of Nations and to the Supreme Economic Council, with the request that all possible assistance be given. Meanwhile, the appeal of the League of Red Cross Societies drew from the Red Cross societies of a dozen nations generous donations of money and materials for the relief of Poland. The Office International d'Hygiène, of Paris, to which a copy of this report was sent, gave its full accord to the recommendation of the League of Red Cross Societies in the matter.

Among the representatives of the League of Red Cross Societies in Poland at present are Mr. William C. Boyden, as commissioner, and Colonel Harry A. Shaw, as medical representative. These officials, with the aid of a medical staff, are prepared to carry on in cooperation with the Polish Government an extensive campaign against typhus and other infectious diseases. This plan includes disinfection of persons, of buildings, of railway coaches and other vehicles of transportation; the establishment of disinfecting stations; the establishment and operation of hospitals, the securing of sanitary personnel, and the maintenance of an educational campaign. The application of these measures on a large scale awaits the action of the League of Nations in furnishing the necessary money and material.

With a staff of seven other scientists, who were recently also in Poland for the League of Red Cross Societies, Dr. S. Burt Wolbach, of Harvard University, is conducting investigations regarding the etiology of typhus, with the ultimate hope that new knowledge regarding its prevention by vaccination and its treatment by serum-therapy may be obtained.

Many national Red Cross societies continue to give freely for the relief of Poland; but it must not be forgotten that the situation there calls for aid on a greater scale than can be expected from any voluntary relief agencies.

Furnish Authoritative Data

It is the second of the three lines of activity of the League of Red Cross Societies which necessarily brings it into the closest touch with the public. The collection and dissemination of medical information is carried on by the General Medical Department, which is subdivided into eleven other departments.

The Department of Medical Information, of which Dr. Thomas R. Brown is the chief, represents an endeavor to keep abreast of the latest contributions to medical science, as well as to compile authoritative data on numerous medical subjects. To take a concrete illustration of this work, let us suppose that a doctor in St. Louis or a hospital in Buenos Aires or a relief nurse in Armenia desires information upon some scientific matter concerning which there is no authoritative opinion immediately at hand. The doctor, perhaps, wishes to know something concerning the rôle of vitamines in nutrition; the hospital may desire information concerning the etiology of typhus; the nurse may be in urgent need of enlightment on some point of nursing procedure.

Imagine, then, that three letters are despatched to the Department of Medical Information. They arrive and are turned over to specialists in the fields to which they apply. These specialists collect the desired information and immediately send it to the questioners. There is, of course, no charge for this service.

At present information can be at once secured on the communicable diseases, such as typhoid, typhus, yellow fever, and influenza, tuberculosis, venereal diseases; malaria, child welfare and nutrition, nursing, and sanitation and hygiene—including hygiene and vital statistics.

A very important part of the service of the Department of Medical Information consists in furnishing, in English, French, Italian, or Spanish, as may be desired, digests of the recent literature upon any subject within the scope of the above list. Information is available upon the present state of knowledge in regard to any question of public health, determined by the literature and by the opinion of the experts of the League of Red Cross Societies. Vital statistics, so far as they are available, either as regards the prevalence of disease or the state of health in different localities, and information as regards the present and future activities of the League in public health matters may also be had for the asking.

Another comprehensive undertaking of this department is the publication of the *International Journal of Public Health*. This is strictly a scientific journal, and is published simultaneously in four languages—the first attempt, so far as is known, to reach in their own tongues such a varied circle of readers with a scientific publication. The first number of this journal, which for the present will be issued bi-monthly, has just appeared, and counts among its contributors men who are internationally known and honored as scientists. It also contains reviews of recent literature in public health fields; a general survey of the health of the world, and notes on the scientific work carried on by the League.

Too much emphasis cannot be placed upon the fact that the Department of Medical Information is not only willing, but anxious, to furnish medical data to all who may desire it. Its service is as concrete and definite as would be that of an encyclopedia which was daily being revised and kept absolutely abreast of all developments in its particular field.

In the future, moreover, in accordance with the recommendations of the Cannes Conference, the League hopes to establish a hygienic laboratory, where new methods of controlling infectious diseases may be demonstrated; and a museum, where new sanitary appliances and apparatus may be exhibited.

Included in the General Medical Department are departments of child welfare, of tuberculosis, of communicable diseases, of nursing, of sanitation, of vital statistics, of social hygiene, of malaria and of industrial hygiene; and a library. To this Department are attached a Counselor of International Public Health, Professor Rocco Santoliquido; and an adviser in Public Health, Surgeon General Hugh S. Cumming, of the United States Public Health Service.

The Child Welfare Department has prepared a scheme of a model child welfare unit which has been printed in booklet form and which is available for all who wish it. A resolution of the General Council of the League, which convened at Geneva in March, urged that such a unit be organized and sent immediately to that country whose national Red Cross Society would be willing gradually to take up the operation of this unit, and eventually to duplicate its activities, personnel, and material. The Department of Tuberculosis, likewise, has prepared a report upon an anti-tuberculosis demonstration; and the General Council also recommended that a practical demonstration of the work which such a unit can do be undertaken in some country where no such organization now exists. These recommendations were approved by the League's Medical Advisory Board, which met July 5-8. Another task which the Department of Tuberculosis has undertaken is the collection of information concerning the tuberculosis situation in various countries of the world.

The most important activity of the Department of Communicable Diseases at this time relates to Poland and the anti-typhus work being carried on there.

The Department of Nursing has organized a course in public health nursing to be given in the King's College for women of the University of London during the scholastic year of 1920-21. This course, for which ten free scholarships have been offered by the League of Red Cross Societies, has been established in order that young women of various countries may be given training in public health nursing and returned to their own countries as pioneers in this work.

"The establishment and maintenance of a clean environment for human beings" is the motto of the Department of Sanitation, which is undertaking field surveys of sanitary conditions, educational work, and the stimulation of national Red Cross agencies to carry on local endeavors for the improvement of sanitation. This Department likewise is prepared to assist and encourage the foundation of a practical training school for sanitary engineers; and it must be remembered that many eastern European countries present the most urgent need for sanitary improvement and the attention of trained sanitary personnel.

The Department of Vital Statistics is attempting gradually to have the vital statistics of all countries standardized and tabulated in such forms that they will be easily comparable. Adequate statistics now are lacking for many countries; and the Department of Vital Statistics will endeavor to impress upon these countries the value of birth and death registration, of the

notification of infectious diseases, and of improved systems of death registration. Coincidentally with its efforts for better methods in the collection of vital records, this Department also is gathering and tabulating for the use of the League of Red Cross Societies a vast amount of statistical material.

The widespread interest now being manifested in the field of social hygiene has been met by the creation of a Department of Social Hygiene which is preparing for presentation to all national Red Cross societies a digest of the laws and schemes now existing in all countries for combating venereal diseases, and which also is attempting to stimulate social hygiene work in various countries.

The Department of Malaria has only recently been organized. However, with the knowledge that malaria is largely a preventable disease, and that it really pays better to take anti-malaria measures than to continue to treat cases of the disease as they arise, as a basis to work upon this Department has already begun the stimulation of anti-malaria campaigns.

The Department of Industrial Hygiene has not yet been placed actively in operation, the reason being that it has been thought better to await the action of the League of Nations on this subject.

Defend Frontier from Disease

At the March meeting of the League's General Council the health of eastern Europe—and that means also the health of the rest of the Continent—was considered in the recommendation for the establishment of a sanitary line of defense from the North to the South at the Russian frontiers. Typhus cannot be satisfactorily dealt with until the streams of typhus stricken refugees which come from Russia are prevented from continually reintroducing the disease into the central European states. Rigid inspection at the frontiers is necessary also, for the prevention of the introduction of other communicable diseases.

The medical recommendations made by the Council of the League are passed upon by the Medical Advisory Board of the League, a body of fifteen distinguished scientists from eight nations, which held its first meeting at Geneva on July 5.

The League of Red Cross Societies has established cooperative relationship with the Office International d'Hygiène Publique (International Office of Public Health), which is particularly concerned wth the international aspect of public health. The relationship will continue after the international office has become a part of the new International Health Organization of the League of Nations; and, inasmuch as the purposes of the League of Red Cross Societies are recognized by the League of Nations covenant, it will be seen that the connection between the two leagues is of the most beneficial sort.

The League of Red Cross Societies is not out to reform the world. It is non-sectarian, non-political, and non-governmental. Its mission is to improve the general health of the world, whether this be done through its member Red Cross societies, or through its own efforts. Its work is planned absolutely on a scientific basis; and the caliber of the men who propose to pass upon its plans, who contribute to its scientific journal, and who indorse and assist its work, is a sufficient guarantee of the soundness of the planning.

There are no bigger names in the medical world today than those of many of the men who are active in some phase or other of the work of the League of Red Cross Societies.

The world is tired—tired of war, tired of feverish propaganda, tired of the hundreds of panaceas and nostrums which are proposed to make it over. It wants to get back to work and it wants to conserve every life that it can; and it is willing to listen to people who can give it sound advice on the attainment of either ideal.

It is here that the symbol of the Red Cross is happily situated. Since its adoption, it has stood above reproach; and the last war fixed it firmly in the popular mind as the emblem of unselfish devotion. Not in the least unmindful of the heritage with which it has begun its career, the League of Red Cross Societies hopes to be able to show the world how to be happier and healthier in its new era of peace.

TWO CHILD WELFARE SCHEMES

An interesting comparison is drawn by G. H. G. Dundas in the *Edinburgh Medical Journal* on the child welfare schemes in Ramsgate, work by a volunteer agency, and that in Leith, which is wholly municipal. "In Ramsgate, educative methods are in predominance; in Leith, curative. In both boroughs the scheme had as its foundation the Notification of Births Act; the standard of one health visitor to every 500 births a year prevails; uniformity of teaching by members of the staff is emphasized; prenatal work is included in the scheme, as are also nursing mothers and children under five years of age; notified cases of measles and whooping cough are visited—by the medical officer to the scheme if the case is notified by the mother, and by the health officer if the case is notified by a doctor. No great hopes are entertained of preventing the spread of measles and whooping cough by notification and visiting, but great hopes are entertained of preventing sequelæ and deaths."

A good workman at his best makes a poor doctor. Do not trust him. Go to the doctor, says the National Safety Council.

INFANT WELFARE AFFECTED BY CLASS DISTINCTIONS AND NATIONAL TRAITS

By A. LEVINSON, Chicago

The application of medical science to physical betterment emphasizes individualistic studies and special methods. Generalizations are possible, however, and collective methods may be called for.

Hereditary factors and the traditional background constitute an integral part of the conditions which affect infant welfare work. Specially trained and carefully adapted workers are essential to successful service.

To such professional skill must be added the social acumen which perceives the varied inheritance of the American people and seeks to preserve all that is constructive in its tendency.

THOSE who handle large groups of mothers and children study their problems not only individually but also collectively and after an extensive experience it becomes possible to group the mothers according to classes and nationalities. Through a varied experience in infant welfare work among mothers of different classes and various nationalities it has been my good fortune to come into contact with women and children representing many lands and many tongues and an opportunity was thus afforded to observe the different customs and characteristics of the people and to come face to face with many interesting problems that confronted the mothers who brought their children to the clinics.

Early in my experience I learned that every mother, like every child, is a problem unto herself. Many are the problems of the mother, especially the young mother, and many are the problems of the child, especially the young child. Some mothers, however, by virtue of their previous history and their present circumstances offer fewer difficulties to the infant welfare station and its attending physician and nurse than do others.

Once in a while one encounters a very rich mother who does not want to nurse her baby because it interferes with her social duties; but this type of mother, though sadly in need of infant welfare instruction, does not frequent the infant welfare stations, and her problem belongs to the realm of the family physician with a lucrative practice who usually knows, or soon learns to know, just how to handle the rich and "fashionable" mother.

The average American or foreign mother is anxious to nurse her baby. Aside from finding it easier than to prepare six or seven bottles a day, she has learned that mother's milk is best for the babe. This constantly growing knowledge of the value of breast milk tends to lessen the difficulties of the mothers and leaves the physician, nurse, and social worker only the task of regulating the feeding of the infant and of suggesting the necessary hygienic measures.

The biggest problem, however, is presented by the poor mother who is anxious to nurse her child but who cannot for financial reasons, for she must go out of the home to add to the family livelihood. Cases such as these call for good judgment and for advice particularly adapted to the individual case in question. In some instances it may be advisable to obtain assistance for the mother from social agencies so that the mother may be enabled to continue to nurse her baby.

In other cases it is best to have the mother nurse her infant twice a day, giving it the bottle at other times. Some mothers solve this problem for themselves by procuring housework near enough to their homes to make it possible for them to nurse their infants every three or four hours. Work of this type, however, is not easily obtainable.

Artificially fed infants present not only problems of infant feeding but, also, problems of a social nature peculiar to various classes of society. These difficulties constantly confront the physician, nurse, and social worker who in various capacities are called on to attend the mother and child. Any advice or suggestions given the mother must be guided by the question of expense. For instance, though the physician may know that certified milk is the purest substitute for mother's milk, it cannot always be recommended to the average mother because of the expense involved. The physician must, therefore, teach the mother how to make ordinary pasteurized milk serve the same purpose so that she may not be tempted to take matters into her own hands and feed her baby condensed milk because it is cheaper than fresh milk.

The same question of expense enters in the choice of a sugar for the baby's milk. The

different malt sugars on the market may be of value, but their price is often prohibitive for the poor mother. The mother should therefore be shown that she can use ordinary cane sugar with almost the same results. Not only in the matter of milk and sugar, but even in the question of a fruit juice must individual judgment be used. Orange juice may not be within the reach of every mother and again the physician must come to the aid of the mother and suggest a substitute fruit juice so that the child may not be deprived of a necessary antiscorbutic.

If the workers at the infant welfare station do not gain the full confidence of the mother the success of their efforts becomes greatly minimized. The mother may continue to visit the station, and yet she may not be carrying out the suggestions so necessary for her baby's welfare because the orders given are not within her means.

Race and Nationality Are Factors

The mothers who frequent the infant welfare stations can be differentiated not only by the strata of society from which they come, but also by the customs and characteristics of the race or nationality they represent. In spite of the cosmopolitan character of these clinics in the large cities the mothers who attend them with their babies may be grouped according to the degree of cooperation they give the physician and nurse, and this factor in turn is found to bear a direct relation to race and nationality. My own experience in infant welfare work afforded contact with three types of mothers from the standpoint of race and nationality: the American (white) mother, the colored mother, and the mother of foreign birth.

The American Mother

The average American mother presents no special problems in connection with infant welfare work except those peculiar to social conditions. Her acquaintance with the infant welfare station often begins when something goes wrong with the baby, when it is irritable, when it vomits, or when it does not gain. At this crisis an "experienced" neighbor usually steps in and advises weaning. Sometimes it is even a doctor who advises taking the baby off the breast. It is in such cases that the mother frequently turns to the infant welfare station. It is here the infant welfare physician or nurse can do a great deal of good by saving the mother's milk for the baby and possibly saving thereby the baby for the mother. Generally speaking, the American mother can be depended upon to follow the instructions given her. Unlike the foreign mother, she has no special superstitions in connection with her babe. Her most flagrant offense lies in the direction of cathartics. She often offends in the matter of overphysicing her infant. However, if warned against the danger of establishing the "physic habit," she is less likely to offend again. The same is true with overfeeding.

The Colored Mother

The colored mother presents a number of special problems in connection with infant welfare. One of the most important problems is referable to the extreme youth of colored mothers, a great many of whom are only sixteen or seventeen years of age. In my own experience there were several only fifteen and a few as young as fourteen. Although some of these mothers did very well despite their extreme youth, one could hardly expect most of them to show great soundness of judgment or mature experience in dealing with their children. It is quite a common sight to behold a young colored woman of seventeen carrying one infant in her arms, and dragging another at her side. One such case, a mother seventeen years of age, gave a story of a child of twenty-two months, a premature babe of five months, and a miscarriage. Were it not for the colored grandmother, who plays a great rôle in such cases, it is very unlikely that more than a very few of the colored babies brought into the world would survive.

Another problem of great importance is the number of illegitimate children among the colored people. Society at the present time is not prepared to care for the illegitimate child if the father has escaped. If the mother could receive some form of support she would be able to take care of the child; receiving none, she must go out to work and board out her child. The child is left without a mother's care, and without breast milk. It is here that the grandmother often enters and saves the situation by taking care of the child. Fortunately, the fate of the mother of the illegitimate child, among the colored, is not so bad as among other peoples. She is not ostracized from society as is the case among other races, and this fact gives the mother a chance to readjust her life and in turn helps the child. The readjustment, however, is slow.

Housing An Important Factor

The housing conditions among the negroes are also a matter of import. This problem, which is acute among the poor of all peoples, is doubly so among the colored, for there is added to the poor housing conditions the lack of appreciation on the part of the average colored mother of the importance of good air and green grass.

Although rickets is prevalent among infants of other nationalities and races, it may be called the disease of the colored infant. It can be safely stated that from 95 to 98 per cent of colored infants suffer from rickets in one form or another. It is true that we have no sure cure for rickets. It develops in spite of all that can be done for the infants, whether they are given breast milk or cow's milk, whether they have cod liver oil or not, and whether or not they have fresh air. The fact remains, however, that rickets is influenced by various factors. The child who gets breast milk is not nearly so prone to have severe rickets as the child brought up on artificial feeding, and the infant who gets orange juice and cod liver oil is not nearly as rickety as the one without them. A knowledge of rickets is, therefore, necessary for good infant welfare work among the colored.

Traditions Affect Child Care

Of no small importance in connection with infant welfare work is the matter of tradition and superstition among colored women. As far as can be ascertained, many of these traditions have no background except superstition. The old calendar and the new calendar are very frequently referred to by the negro mother. A chain of allspice, a chain of Job's tears, a crumb of bread, a piece of asafetida, or a forepaw of a rabbit is frequently suspended from the infant's neck. Bathing in dishwater and in cabbage water is very frequently practised on the infants. A knowledge of these superstitions is valuable, however, not for the purpose of interfering with them, but to enable one to know which of these superstitions interfere with hygienic rules. Most of them do not interfere with good hygiene, and to advise against them merely serves to antagonize the mothers and results in lack of obedience on their part.

Mothers of Foreign Birth

In dealing with mothers of foreign birth one is at a distinct disadvantage if he does not understand the language they speak. If every physician, nurse, and social worker in a foreign district could understand the language of the people among whom they work, the results of infant welfare service among foreign mothers would be far better than they are at present. Attempts to meet this difficulty are being made by some infant welfare societies, who are beginning to assign foreign speaking physicians and nurses to work among their own people.

The foreign mother, to a much greater degree than the native American mother, does not see the necessity of going to see a doctor or nurse with a well baby. The nurse or social worker, however, can do a great deal to educate the foreign mother in this direction by frequenting her home and pointing out the assistance the infant welfare station can be in maintaining the health of her babies.

The economic problem, which is a great factor in infant welfare work among the mothers of American birth, is much more acute among women of foreign birth. Several years are usually required for an immigrant family to adjust itself economically. Many foreign mothers have to assist in the earning of a livelihood and they cannot, therefore, devote their entire time to their children. This is most common among Polish and Bohemian mothers. It is less frequent among Italian mothers, and very rare among Jewish mothers.

A great problem among the foreign born is the large families most of them have. The foreign born do not practise birth control to any great extent. Six or seven children under the age of ten are not infrequently encountered in families whose wage earners make but a poor living, a condition which makes it doubly hard for the baby, who thus receives only a small share of the attention it needs.

Some Points of Contrast

In several respects the foreign mother presents some interesting contrasts to the American mother. She is bound by traditions that react on her baby. Italian mothers bandage their babies very tightly to straighten out their bones; Chinese mothers compress the feet of their babies to prevent them growing too large; Austrian mothers give their babies beer and wine to make them strong.

In the matter of clothing, the American and foreign mother stand at the two extremes. The average American mother, in her fear of overdressing the baby, dresses it in sheer, summer garments and thin cotton underwear the year around. To inure her baby to the cold, she takes it out for an airing even when the thermometer registers below zero. The foreign mother, on the other hand, in her fear of under clothing her baby, bundles it up in woolens and flannels and, to prevent it taking cold, she keeps it indoors with windows closed.

The foreign mother adds solids and semi-solids to her baby's diet at a very early age. I have seen babies as young as one month of age fed Zwieback, thus going to extremes, just as some American mothers go to the opposite extreme of withholding semi-solid food until their babies are eight or nine months of age.

In the matter of breast feeding, the foreign mother often makes a fault of a virtue. She nurses her baby faithfully enough but, as a rule, too frequently and over too long a period. Many foreign mothers nurse their babies up to the age of eighteen months or more. The reasons given for prolonged nursing are various. Many consider that it is to the best interest of the child; that if eight months of breast milk is good, eighteen months should be better; or, the breast feeding is continued because nursing the baby is easier than preparing bottles for it. No small proportion of the cases of protracted nursing is centered in the hope that it will serve as a preventive against conception.

The foreign mother can be rendered very amenable to instruction if she is treated with consideration and kindness. First of all, she must be understood. Most foreigners come from countries where the average citizen is afraid of an official, and many of the foreign mothers look upon the nurse or social worker, and even upon the physician, as government officials who come to make an investigation in order to punish them afterwards. The infant welfare worker among foreign born mothers must, therefore, first of all, try to remove the "official" fear idea. It gives way in a short time to sympathy, kindness, and understanding. As soon as the mother is convinced of the good intentions of those who come to advise and assist her in the health problems of her young, she can be depended upon not only to follow the instructions herself, but to spread her influence to her neighbors.

CHILD WELFARE WORK IN SOUTH AFRICA

A reviewer in the June issue of the *British Journal of Children's Diseases* reports interesting progress in child welfare work in South Africa. Subsequent to the disastrous epidemic of influenza all past public health legislation was consolidated in one Act and a Minister of Health appointed.

PEDIATRICS IN CHILD WELFARE

Pediatrics is but one special branch of the cause of child welfare, according to the *British Journal of Children's Diseases*, June, 1920, in reviewing the work of A. Dingwall Fordyce. The care of sick children must include (1) a more thorough and systematic training of medical students; (2) greater facilities for efficient treatment; and (3) better facilities for retaining health. A very important phase of the work depends upon improved housing and lighting, further development of play centers, kindergarten and day nurseries, and upon the stringent supervision of boarded-out children. One of the chief advantages to accrue from the development of child welfare centers, he emphasizes, is the extension of medical superintendence from the periods of disease and convalescence to times of health.

MAKING AMERICA SAFE FOR BABIES

IN order to test the value of a traveling health center for remote communities, the United States Children's Bureau has equipped and is sending out a big automobile truck as an up to date "well baby clinic." This child welfare "Special" is in charge of a government doctor and a nurse.

The big car halts at designated points and immediately

Underwood & Underwood.

All aboard for Healthy Town on the Child Welfare Special! One method to be used in making America safe for babies.

becomes the center of interest. As soon as its object is noised about, mothers begin to appear with their children. As its purpose is to keep well babies well, no medical aid is given, but thorough examinations are made to see if the babies are growing as they should. In addition, mothers are given advice and instructions as to how to properly care for their little ones.

This oral instruction is supplemented by a child welfare exhibit which travels with the special, and which is set up in a church or school house near the big car's parking place. While the mothers await their turns to have their children examined, they learn many things that are of advantage to them in the care of their babies. The exhibit consists of posters giving information which every mother should have, sample cribs, beds, a playing pen, screens, and bath utensils. Sample garments of the proper make and materials are pinned on a sheet which is attached to the wall.

Underwood & Underwood.

Child welfare exhibit which mothers are privileged to examine while awaiting their turns. Ocular proof of how things are done makes the doing easier.

Underwood & Underwood.

The nurse who travels with the "Special" is testing the sight of this wee miss, impaired vision being one of the most common defects found.

The spick and span whiteness of the interior of the car with its compact built-in equipment suggests the sanitary arrangement of a hospital operating room. Here the mothers bring their youngsters—the pudgy and the lean—and all are put through their paces to see whether or not anything is wrong. A record is made of the findings, and then detailed instructions are given to the mothers along the line of improvement in their methods of handling their babies, and of measures necessary to prevent disease.

The chief work of the "Special" is to call attention to defects, where they exist, in time for remedial measures to be effective. One of the most important examinations made is that of testing the eyes, and the nurse who travels with the special must be able to make these tests. Three-fourths of the 22,000,000 school children in the United States have health defects which are injurious to them as prospective citizens.

In some sections of the United States even though the last frontier has vanished, many babies are born and are growing up under pioneer conditions. In one of the western states an agent of the Children's Bureau discovered a territory 5,500 miles square where there was not a single telephone, and where most of the families lived more than twenty miles from a doctor—a distance made much longer by bad roads. In time it is hoped to by means of the "Special" to put medical attention in reach of every baby in these isolated districts.

Underwood & Underwood.

The "Special" will bring relief to thousands of Prairie Madonnas in their dugout homes.

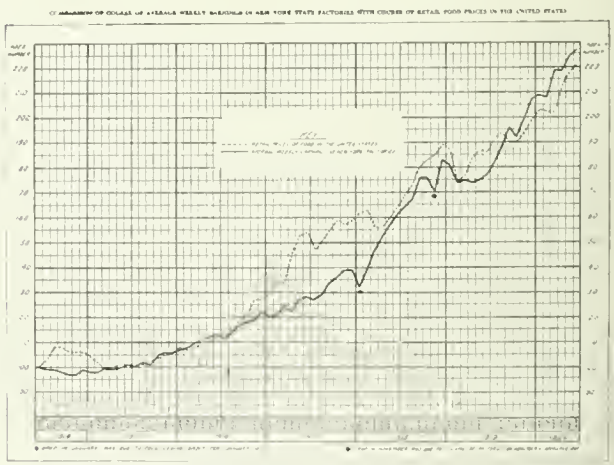
A MENTAL HYGIENE PROGRAM FOR NURSES

The nurse is a disciple of mental hygiene as well as medical hygiene, says Dr. William Barclay Terhune in the July issue of the *American Journal of Nursing*, arguing in favor of a mental hygiene program for nurses which would demand that all nurses receive, as a part of their fundamental training, psychiatric instruction associated with demonstrated clinical material. The pathfinders in psychiatry have carefully marked and described the way, so that whether they elect to enter this field through psychology, clinical psychiatry, psychiatric criminology, industrial psychiatry, or psychiatric social service, the educational way is open, the opportunities unlimited, and the potential usefulness of the nurse increased in every direction. No time should be wasted in theoretical study that does not offer clinical advantages in the subject.

In the universal training of nurses on the psychiatric phases of their work lies the hope of detection and correction of abnormal and unsocial tendencies before they become crystallized as an integral part of the character, and the possibility of training the handicapped so as to compensate for psychic difficulties.

Mental nursing is now almost wholly confined to private homes and mental hospitals, but there is no reason why general hospitals should not have active psychopathic services. Mental disease is practically the only form of illness barred from general hospitals, and such discrimination is unwarranted.

A COMPARISON OF PAY WITH PURCHASING POWER



This chart shows a graphic comparison of the average weekly earnings in New York state factories with the course of retail food prices in the United States. *Labor Market Bulletin*.

AMERICAN JOURNAL OF PUBLIC HEALTH

There is little doubt that most of the physicians in the United States desire a national department of health, stated Dr. Seale Harris in his presidential address before the American Medical Editors' Association in New Orleans. The present United States Public Health Service should be its nucleus. If any advanced legislation for public health is enacted within the next few years it is time that the organized medical profession organize for a systematic campaign. Public health is a business proposition. The medical men know the need and should take the foreground in presenting the matter to the people and to legislators. The August issue of the *American Journal of Public Health* presents the salient arguments on this subject made by Dr. Harris.

PSYCHOANALYSIS RESTATED

SEVERAL generally current notions in regard to psychoanalysis are proved fundamentally wrong by the authorized translation by G. Stanley Hall[1] of the lucid and simple statement of the tenets of psychoanalysts. Freud definitely urges against these generalizations of his statements which lose sight of the fact that all his observations are based on the study of a single group of nervous affections—the so-called transference neuroses. He rejects as far as possible the rôle of mentor; advice and guidance are not to be regarded as an integral part of analytic influence. "We are not reformers, only observers," he says; " . . . Our usefulness consists in replacing the unconscious by the conscious, in translating the unconscious into the conscious. . . . Where no suppression and no analogous process can be undone, there is no place for our therapy."

The limitations of the method are admitted with a frankness that bespeaks the honest and painstaking quality of his research. The structure of psychoanalysis so far is really only a superstructure, he says; the task remains to place it on its organic foundation. Psychoanalysis may not even be termed causal therapy, as would be the case if it were possible to influence these functions chemically instead of being compelled to employ the circuitous method of first finding the suppression and then removing the resistance by which the suppression is maintained, a result achieved by rousing a counter impulse to set over against the offensive impulse and thus inducing a normal psychologic struggle, possible of solution, which replaces the pathologic conflict of the neurotic. In the hands of Freud this method has been successful in a large number of forms of anxiety and compulsion neuroses, but its failure in cases less accessible leads him to express a doubt whether he has really understood all the conditions of success in other neuroses.

We are often able to see in maladjustments the element of compromise wish-fulfillment and are willing to concede the existence of processes of unconscious mentation which have a meaning that escapes exact science. The psychology of Freud is in line with leading schools of thought in seeking a dynamic conception of psychic phenomena. The whole nomenclature of mental science points to energy released or countered or pent up: impulses, stimuli, idea forces, resistances, conflict, being definite expressions of this trend. Associations are conditioned, mental sets are formed, reactions are predetermined and their relative intensity governed by the constitution and experience of the patient. It is even clear that we

1. Freud, Prof. Sigmund, LL.D.: A General Introduction to Psychoanalysis. Authorized translation by G. Stanley Hall. Boni & Liveright, New York, 1920.

forget through the same mechanism by which the memory is strengthened. Nothing is accidental. Dreams, unfulfilled desires, even haphazard thinking, furnish clews to personality distortions and their relationships; but it remains that much ambiguity attaches to the realm of the unconscious, and it does not seem essential to limit the inhibitory organizations of the materials of the unconscious to morbid processes of the libido. A broader interpretation might come closer to fulfilling the requirement of science that a solution must be universally true.

However, "preferences and dislikes are not the proper bases of scientific judgment" and the studies of Freud are distinctly illuminative. The early chapters on the psychology of errors and the mechanism of dreams elucidate much to account for the potentialities for perversion. He finds that all inclinations to perversion have their origin in childhood. He does not, however, find the remedy in childhood prophylaxis. The person cured of a neurosis by the laborious method of psychoanalysis becomes another person through a change of attitude,—a not insignificant accomplishment.

The process by which the child is said to fill "the gaps of individual truth by historic truth" is not so readily acceptable and the more or less arbitrary symbolism which all leads to the single interpretation that these "antiquities of human development" are resorted to as substitute satisfactions is not patent without research into a realm of psychology which constitutes a field in itself. From the viewpoint of the patient the whole matter turns on the social experience. In an unsatisfied person, turning away from reality and transforming all his wishes to an elaboration of imaginary desires and satisfactions easily points the way to neurosis. A social code may demand more sacrifices than it is worth, and in a given case such a neurosis may be the best adjustment possible under the circumstances.

Science and ethics become involved in the pursuit of the subject. The appearance of this text is highly opportune. The conversational discourses afford the best possible substitute for the lecture room, and the results of this study demonstrate anew the possibility of illuminating the processes of normal mentation through the painstaking analysis of abnormal psychology. S. P. M.

CHILD HYGIENISTS MEET

THE American Child Hygiene Association, previously known as the American Association for the study and Prevention of Infant Mortality has taken on new and broader activities with its new name. The Society no longer limits its activities to the prevention of infant mortality, but interests itself in the many problems of infancy and childhood from the prenatal period to that of adolescence.

The program of the annual meeting of the Society, to be held in St. Louis October 11-13, shows the extensive scope of the activities of the organization. The program will include a discussion of prenatal and maternal care, a round table talk on state and city divisions of child hygiene, a session on the problems of pre-school age and of adolescence, a presentation of rural health problems, a discussion of nursing and social work, of infant care, and a session on vital and social statistics. The discussions will be carried on by men and women vitally interested in child hygiene.

The Society is now publishing a monthly magazine, *Mother and Child*, devoted to the welfare of the mother and the child. The two issues that have thus far appeared are very commendable. They contain good reading matter couched in non-technical terms, which should appeal to physicians, nurses, and social workers, and even to the laity.

The activities of the Society during the last year, since the widening of its scope, have been very fruitful. It is hoped that the next meeting, which will mark the eleventh year of the organization's activity, will bring forth new and broader activities in the interests of the child.

STUDIES ON DIABETES MELLITUS

THE recent literature on diabetes mellitus is characterized by two distinct phases of activity, the one dealing with the disease as a chemical-pathological problem, and the other with the treatment of the individual patient. Allen[1] has contributed new studies in the pathological physiology of the disease on the basis of animal experimentation. Mosenthal and Wiener[2] have just published diets for the ambulant treatment of the disease. These diets are based on the assumption, which has been so often emphasized, that successful therapy of the diabetic necessitates the most painstaking care in dietary regulations after the patient leaves the institution. By means of the diets published by Mosenthal and Wiener a patient with any degree of intelligence can work out for himself just what diets to follow at given stages of the disease. Lauritzen,[3] of Copenhagen, also treats of modern individualized treatment in diabetes. In this article all kinds of diabetic patients are discussed, diet is given in detail, and, although the article adds nothing particularly new, it is a very good régime, especially for teaching purposes. Strouse[4] in a recent article emphasizes the point of view that the diabetic patient is essentially no different from any other patient in internal medicine and that proper therapy depends on complete individualization of each patient. He emphasizes the need of paying more attention to the history and physical examination, and of placing proper relative values on all the data obtained, history, physical examination, food intake, and laboratory findings.

This inclination to emphasize the necessity of individual therapy is an excellent tendency. Investigation will be of little avail to the diabetic patient unless the physician treating this patient knows how to apply to his individual case the lessons learned from the more intensive study.

SPINAL ANESTHESIA

MANY American physicians who, during their service with the American Expeditionary Forces, had the opportunity to visit the larger French clinics were surprised to note the frequency with which spinal anesthesia was employed. Although first discovered by an American, the method is much more widely used in Europe than in America, and is especially popular in France, Roumania, Germany, and Austria.

J. L. Corning published the reports of his experiments in 1885 in the *New York Medical Journal*. Bier of Berlin and Tuffier of Paris, after the work of Quincke, rediscovered spinal anesthesia. These surgeons used cocain exclusively. Because of the great number of mortalities, the method soon fell into disrepute and it was not until after Fourneau's discovery of stovain, in 1904, that it was again adapted.

Wertheim and Shauta of Vienna have employed spinal anesthesia in nearly all cases in their gynecological clinics for years. In Marseilles Professor Imbert has been using syncain for practically all pelvic operations.[1,2]

Jonnesco, the Roumanian surgeon, however, made the widest use of spinal anesthesia, and to him belongs the honor of devising methods for its use in operations ranging from the scalp to the toes. He published in 1914 a report from his own clinic and that of other Roumanian surgeons of a series including 11,324 operations under spinal anesthesia, of which 10,289 were lumbar punctures, and 1,035 cervical or dorsal punctures, with only two deaths.

Various different anesthetics are employed—cocain, novocain, tropococain, stovain, apothesine, syncain, and procain. Cocain is generally conceded to be dangerous, although Wells[3] states that Paul Dalmar of Montpellier, France, has been using anhydrous cocain successfully for operations in practically any part of the body. Jonnesco uses stovain and strychnin, but claims that it is not the nature of the anesthetic drug but the method used which is the important factor. Any local anesthetic which is strong enough, but not toxic, will serve.

Various methods are employed to bring about anesthesia at a desired area. Some surgeons employ a mixture which has a higher specific gravity than the cerebrospinal fluid and, after the introduction of the fluid by lumbar puncture, they change the position of the patient. Others use a fluid of a lower specific gravity. Still others first aspirate a large quantity of spinal fluid, and reach the different levels by forcing the anesthesia in with a varying amount of pressure. Jonnesco anesthetises the desire segment of the body by injecting the anesthetic at different levels of the spinal cord.

It is our desire here to review briefly Jonnesco's method,[2] taking as a basis a recent article and his book "La Rachianesthésie Génerále."

Jonnesco claims that, with very few exceptions, practically every operation can be conducted successfully under spinal anesthesia. Inasmuch as the anesthetic acts especially upon the nerves near the site of its introduction, he changes the level of his punctures as the case may demand. Four sites for injections are used: (1) The "mid-cervical" site, for operations on the head, scalp, face, or pharynx, lies between the occipital protuberance and the *vertebra-prominens, i. e.*, between C 3 and C 4 or C 2 and C 3. (2) The "cervico-dorsal" or "superior-dorsal" point, for operations upon the upper part of the chest and upper extremities, is between the *vertebra-prominens* and the next lower vertebra, C 7 and T 1 or T 1 and T 2. (3) The third site is the "lower dorsal" or "dorsal lumbar," at the level of the lower border of the twelfth ribs, used for abdominal operations and for operations on the lower extremities. (4) The usual lumbar puncture site, namely, at the level of the iliac crests, is called the "lower lumbar" site, and is used for pelvic and perineal operations. Jonnesco has found it best at times to divide the dose between two sites—thus, for operation on the entire thorax or for long operations involving the abdomen and the pelvis—gynecological operations, for example—the dorsolumbar and lower lumbar sites are chosen. A shifting of position is also used, but to a slight extent, as he considers that the fluid diffuses better in the direction of gravity to only a very small degree.

Jonnesco uses a 1 cc. syringe in conjunction with a 6 cm. fine platinum needle, with a stub point.

The anesthetic is mixed just prior to injection, by dissolving the sterilized stovain in 1 cc. of a sterile aqueous solution of strychnin sulphate. The drugs are put up in separate ampules. The purified stovain is in crystalline form in ampules containing amounts increasing one-half centigram from one-half centigram to six centigrams. The strychnin sulphate, dissolved in 1 cc. of water, is put up in ampules containing one-half, one, and two milligrams of strychnin. After having decided upon the dosage to be employed, the strychnin solution is aspirated with a syringe and ejected into the ampule containing the desired amount of stovain. The solution of the stovain is aided by the heat of an alcohol flame. When thoroughly dissolved, the 1 cc. solution of strychnin and stovain is again aspirated into the syringe and is ready to be injected. Ten to fifteen minutes before the injection it is advisable to give 0.25 to 0.50 gms. of caffein hypodermatically.

The injection is preferably made with the patient sitting up and bending slightly forward. Only enough spinal fluid is allowed to flow to demonstrate that the needle has entered into the arachnoid space. When the fluid is bloody, it is best to let it flow until clear before injecting. At the end of the injection a few drops of fluid are aspirated into the syringe to make sure that during the maneuvers associated with the injection the needle has not been pulled or pushed out of place. The patient is immediately placed in the decubitus position.

The dosage varies with the length and severity of the operation to be performed, the general condition of the patient, and, especially, the site of injection. Larger doses can be given for the low injections. The dosage for the mid-cervical and upper dorsal injections varies between 0.005 and 0.02 gms. of stovain and 0.0005 to 0.001 gms. of strychnin sulphate. For the dorsolumbar and lumbar sites from 0.02 to 0.06 gms. of stovain and from 0.001 to 0.002 gms. of strychnin. When injections are made at two sites, the doses are divided one-third for the upper and two-thirds for the lower. For children under four years the maximum dosage is 0.005 to 0.01 gms. of stovain and 0.0005 to 0.001 gms. of strychnin. Over this age the stovain can be given in larger quantities, but never more than 0.001 gms. of strychnin should be given. The aged and the cachectic, likewise, receive smaller doses.

The position of the patient plays but a slight rôle in the effectiveness of the anesthetic; however, head cases are usually operated with the head slightly lowered, and pharangeal cases with the head over the edge of the table. For perineal work or operation on the lower extremities

a "semi-Fowler's" position is used. The Trendelenburg position is used whenever advantageous to the surgeon.

Certain symptoms are to be expected and looked for, irrespective of the site of injection; these are temporary pallor, sweats, a temporary drop in blood pressure, and an increase in pulse rate. Nausea occurs in from 5 to 8 per cent of the cases, but it is usually of short duration and is not followed by vomiting. Vomiting occurs in 2 to 3 per cent of the cases; it is usually but a single emesis, and is followed with cessation of other symptoms.

Interesting variations are found in the respiration, depending, first, upon whether the patient breathes with the abdominal or thoracic type and at what level the injection is made. Following a mid-cervical injection in a patient who presents the two types combined, the thoracic respiration will become exaggerated in rate and amplitude, while the abdominal respiration will diminish and finally stop altogether, gradually reappearing, when, about twenty minutes after the injection, it will resume normal. The thoracic motions gradually diminish to normal. In a case with only the abdominal type, the thoracic type will appear, strong to say, and the above mentioned changes will take place, the thoracic type disappearing again as soon as the effect of the anesthetic has terminated. In a superior-dorsal injection it is the diaphragmatic type which increases and the thoracic which stops.

Notwithstanding these respiratory changes, Jonnesco claims that only very rarely has he had to resort to artificial respiration. It is significant that in eleven years he has known of only three deaths from respiratory failure, and that in all these cases he claims more than the prescribed maximum dosage was given.

Among the after-effects, headaches were noted in 6 per cent, usually this symptom being easily controlled with pyramidon; backaches are rare; nausea and vomiting are not encountered; urinary incontinence or retention occur only after operations which might in themselves cause this condition. Irrespective of the anesthetic, paralysis seems to be restricted to the *N. oculomotoris*, and only five instances of this complication have been reported.

As far as contra-indications are concerned, Jonnesco confirms that spinal anesthesia virtually has none, inasmuch as neither age, general condition of the patient, changes in any one organ, speak against this form of anesthesia. R. B. B.

THE PRESENT SITUATION IN CANCER

THE rôle of chronic irritation as a factor in the causation of cancer is becoming more important and some of the evidence gradually being accumulated is interesting and curious.

The Kangri basket of the Kashmir natives is a rather famous chronic irritant. It is a basket of warm charcoals carried in front of the abdomen or placed between thighs and knees, and is responsible for a marked increase in carcinoma of the skin in these people. In China carcinoma of the esophagus and mouth is common among men who eat their rice quite hot; but among women, all of whom eat after the men folks, it is not so common.[1] W. J. Mayo has recently commented upon the heat of ingested foods as a possible cause of upper alimentary cancer in civilized communities, natives who do not cook their food having far less incidence of cancer of this region. Hot porridge is generally ingested at 163° F., rice at 168°, and hot liquids in general range from 120° to 170° F.

Bertillon[2] once divided France into two squares, one centering about Paris, the zone of greatest alcohol and meat consumption, and the other bordering on the Mediterranean, where these habits are much less in evidence. The upper square had two to four times the cancer incidence of the lower, and the increase was chiefly in cancer of the stomach and rectum.

Imperfect combustion of coal probably is a cancer irritant of some sort; for while coal miners have a low mortality, in workers about gas works and coal heavers about boilers and engines the death rate from cancer is relatively high and English chimney sweeps had a cancer mortality[3] five times that of normal, this last being due chiefly to cancer of the scrotum and being attributable to the direct irritant action of soot. On the continent, where precautions as to clothing were taken, there was no such inordinate increase. A Japanese pathologist[4] has developed cancer in the rabbit, an animal normally very resistant to cancer, by repeatedly painting its ear with coal tar.

Dermatologists[5] see cancer in such processes of long standing irritation, as lupus, psoriasis, and chiefly in persons whose skins have been exposed over long periods to light or heat.

In countries where the breasts are continually exposed and free there is much less carcinoma of the breast than in civilized communities.[6] Many other and even commoner instances could be cited in which cancer starts at the site of some long standing irritation.

Whether cancer is really on the increase, or whether the apparent increase everywhere reported is due to improved diagnosis, differences in longevity, and improved registration, is still an open question. Certain it is that every statistical survey reports an increased cancer mortality. From 63 deaths per 100,000 population in 1900, to 81.1 deaths in 1915, representing an increase of nearly 30 per cent, are the figures from the United States Registration Area. These statistics cover roughly 75 per cent of the population. During this same period the death rate from tuberculosis fell[7] from 202 to 145 per 100,000. In New York City[8] the general death rate for 1919 has fallen 23 per cent over 1918, but the recorded cancer deaths have increased 4.6 per cent. Throughout the world there are similar steady increases. Thus, from 1896 to 1910, while the United States increased 18 per 100,000 in population, Ireland increased 20 per 100,000, Denmark 18, Germany 13, and Austria 10.[9] Cancer will take one man in eleven, and one woman in seven.

To what extent can this apparent increase be explained by varying degrees of accuracy in diagnosis, and to the increased longevity of the present day? Since the civil war, fifteen years have been added to our normal expectation of life.[6] German vital statistics estimate a difference of twenty-five years in the length of life between the Prussian of 1860 and of today. Dogs and cats, the only animals who in nature are allowed to live out their normal life in any great numbers, have a high frequency of cancer.[4] Certainly all mortality statistics have to be corrected to ascertain the proportion of inhabitants reaching cancer age before inferences can be drawn. English statistics have long been so corrected; but since United States

statistics are still not corrected for this factor, and since the death registration area comprises only 75 per cent of the population, conclusions based on American sources must be accepted with considerable caution (Bainbridge[9]).

English statistics[10 11] have long been studied with reference to the question: Is the increase of cancer incidence apparent or is it real? Carcinoma in some regions of the body is much more accessible to physical diagnosis than in others and, if recognition being steadily increasing were responsible for the higher present day statistics, the curves of the accessible organs might remain flat, while the curves of the inaccessible organs would steadily mount. This supposition was substantiated by analyses over a period of two decades. While cancer of the skin and of the uterus, both easily accessible to physical examination, showed no increase, alimentary cancer everywhere showed a rising curve. The male has much more carcinoma of the alimentary tract than the female, and all statistics show that carcinoma is increasing much more rapidly in the male than in the female. Bashford thinks these differences are due to differences in accessibility to physical examination. From London Hospital statistics of 1904-1909, classifying growths as accessible or not accessible to physical examination, Bashford estimated that 91 per cent of the accessible growths were diagnosed, while only 62 per cent of the inaccessible ones were recognized. Another factor Bashford and Murray hold responsible for the increased recognition of today is a gradually decreasing tendency to ascribe "failing vital functions in the aged as a cause of an obscure illness," *i.e.*, fewer deaths are reported as due primarily to "old age." While the curve of cancer mortality from forty to fifty years of age has been relatively stationary for some years, the reported mortality in the aged has been relatively increasing. Summing up, they state that as regards cancer mortality, "England of today compares with England of several years ago, as London of today compares with rural England of today."

However, these analyses are not everywhere accepted as fully explanatory. Ewing[12] says they probably account for a large proportion of the increase, but there still is a certain amount of the increase unaccounted for. Bulkley,[7] who believes that cancer is a systemic disease, and that local excision of the tumor does not cure it any more than cutting off a gouty toe cures gout, has no patience with arguments such as these.

What has surgery done for cancer, and what hope of cure does it offer? Some writers are not optimistic. Whether or not surgery obtains a cure depends on two factors: (1) The presence of distant metastases, often unrecognized at the time of operation; and (2) the completeness of the surgical removal and the possibility of grafting or dissemination of carcinoma cells at the time of operation.

Levin[13] describes the body defense against carcinoma metastases as the formation of a connective tissue capsule. Carcinomatous emboli occur with great frequency, and are transported everywhere. The reason they do not form metastases oftener is because the connective tissue encapsulation is an immediate protection. In carcinoma of the abdominal viscera emboli are encapsulated with great frequency about the small arteries of the lungs. In bone carcinomatous emboli lodge in the lacunae, act as osteoclasts, break down some of the bone, then this space fills up with carcinoma. This mass is surrounded by connective tissue fibrils and, later, a bony capsule is deposited about the irritating focus. Whether or not the body or the carcinoma triumphs depends largely upon the local immunity of the organ, "the metabolic affinity between the carcinoma cells, and the cells of the particular organ." A carcinoma embolus may remain encapsulated for years and then suddenly, presumably because of some lowered resistance, it will burst forth into a metastasis. Here is an explanation of metastases occurring years after operation. The varying degree of immunity possessed by different people has often been commented on clinically. The late J. B. Murphy[14] often spoke of the "rebelliousness of cancer when it occurs with obesity," and remarked that "the thin spare type has a tendency to the production of connective tissue preventing the spread of malignant cells." W. J. Mayo[6] says that, whereas all persons have a certain measure of immunity, some having sufficient to prevent their ever having cancer, in others, it may exist to such a degree that an incomplete operation will not be followed by recurrence.

Grafting, dissemination of carcinoma cells, or incomplete removal at the time of operation are commonly known sources of recurrences. W. J. Mayo states that he has often been impressed by local grafting of carcinoma cells, such as recurrences at the site of skin suture holes only, or recurrence about a colostomy wound from a low sigmoid growth. Once the regional lymph glands are involved the outlook is altogether different, and incomplete removal, no matter how careful and skillful the dissection, is the rule.

Carcinoma of the lip is one of the most favorable malignant tumors operated upon as regards ultimate cure. When no glands are involved, various statistics show 70 to 80 per cent of cures. In a recent study of the material at the Mayo Clinic, Broders[15] shows that 76 per cent of cancer of the lip without glandular involvement are still living; of those having glandular metastases, only 17 per cent are alive, and all of these had involvement of only one submaxillary lymph group. No case with two groups of glands involved, or with cervical glands affected has been reported living. Bevan[16] says that from his personal experience, he does not think he has ever cured a carcinoma of the breast with axillary involvement.

To arrive at an estimate of just what surgery has done for cancer Levin[13] compiled a table of the reported results from various surgeons and clinics. In one column are placed the figures of cures reported from the best operators and clinics (Halsted of Johns Hopkins; Willy Meyer of New York; The Mayo Clinic, Rochester, Minn.) and in the second column, called a low estimate, the reported results are given from other operators, presumably not so skilled.

REPORTED CURES OF CANCER

PERCENTAGE OF FIVE YEAR CURES OF OPERATED CASES

Chiefly Metastatic Cancer	*High Estimate*	*Low Estimate*
Bladder	30	6.8
Breast	38	16
Head, face and neck	83	30
Liver	None	None
Mouth and tongue	20	13
Rectum	50	9
Stomach	25	3
Abdomen	12	4

If the average operability be taken as 50 per cent, the surgeon refuses to operate upon about 50 per cent of the

patients presenting themselves to him because of this advanced stage, and a comparison of the average of these cures with the cancer incidence taken from Mortality Statistics, there is obtained an estimate of just how much cancer is cured surgically. Doing so, Levin says that the best surgeons cure 15 per cent of cases. If all patients came to the surgeon in time, that is, if the operability were 100 per cent, and if all surgeons were as successful as the best surgeons, there would only be 30 per cent cures. At present 10 per cent are cured.

But statistics like these are changing. The limits of operability are widening. At the Mayo clinic[6] when 25 per cent of carcinomas of the intestine and rectum were deemed operable, the operative mortality and the percentage of five year cures were greater than now. As an increasing proportion of the further advanced cases were operated upon, the operative mortality and the precentage of five year cures diminished; but, instead of curing 13 in each 100 patients presenting themselves, 27 are now cured.

People are gradually learning to seek advice earlier, and more often than formerly present themselves before a precancerous condition has become malignant. Bloodgood[17] says that the incidence of benign tumors of the breast has risen at Hopkins from 32 per cent to 59 per cent of the total breast tumors, and the surgeon is nowadays called upon much more frequently than formerly to decide upon the nature of a borderline tumor.

HARRY G. SALZSTEIN.

BRITISH MEDICAL ASSOCIATION MEETS AT CAMBRIDGE

BY OUR LONDON CORRESPONDENT

THE eighty-eighth annual meeting of the British Medical Association was held at the university town of Cambridge from June 24 to July 3, last. This was the first full meeting since 1914 and everything conspired to make of it a success. The place of meeting was almost ideal. Cambridge is situated on a main line about fifty miles from London and, being a large railway center, is easily accessible from all parts of Great Britain. In addition it is peculiarly well adapted for a meeting of this character, both from the scientific and social aspects. The meeting was well attended—there were several well known American surgeons and medical scientists among those present—and the papers read and the discussions thereon were, generally speaking, of a high standard. It may be said that the meeting was especially interesting as it marked a new phase of medical practice. The trend of the chief addresses and of the papers read at the most important sections was in the direction of preventive medicine. The policies of the Ministry of Health as exemplified in the interim report of its Consultative Council were freely discussed and subjected to a good deal of destructive criticism.

A Question of Ethics

The first three days of the meeting were given over to the deliberations of the delegates to the British Medical Association and were productive of valuable results. That is to say, many matters of great moment to the medical profession were more or less threshed out and, if not settled, were considerably elucidated. For example, the question of professional secrecy was dealt with and the following motion was adopted after protracted discussion: that, having further considered the question of professional secrecy, veiwed from the standpoint of the medical profession and with especial regard to venereal diseases, the Representative Body reiterates the opinion that a medical practitioner should not without his patient's consent voluntarily disclose information which he has obtained from such patient in the exercise of his professional duties.

A recommendation of the Central Ethical Committee was also adopted to the effect that a registered medical practitioner should not make use of nor recommend any remedy of which the principal ingredients are not disclosed. In the discussion on this subject it was shown that there was much difference of opinion, it being held by some of the speakers that there were remedies the composition of which was not known but which had proved of value in sickness.

Whole Time State Service Opposed

The most important part of the deliberation of the delegates was that which concerned the report of the Ministry of Health Committee dealing with the Interim Reports of the Consultative Councils on Medical and Allied Services. This report was in favor of the scheme or schemes proposed in the Interim Report, promising, of course, that the said Reports were interim and not final. An amendment to the adoption of the Committee's report was put forward and Sir James Barr characterized the reports as idealistic and not practical. He declared that if the plans suggested in the Reports were carried out as they should be it would take £100,000,000 ($500,000,000) a year for the first five years and £150,000,000 ($750,000,000) a year for the next ten years. The Representative Body was asked to see that the general principles of the reports were more clearly defined, the representativs had not had time to digest the arguments. A unanimous resolution was passed against the principle of a whole-time state service.

The meeting proper of the Association opened in the University Senate House on the evening of June 29, when Sir Thomas Clifford Allbutt delivered his address as president of the British Medical Association. The address was a particularly brilliant review of the work done by the universities in medical research and practice. The speaker inveighed in strong terms against the modern system of cramming for examinations. Referring to the position of the family practitioner and the manner in which state or official control is coming into vogue, Sir Clifford said that for some years past a few of them had been protesting against the clipping of family practice by official shears. They saw the subjects of infectious fevers carried into isolation, and the tuberculous and syphilitic disappearing with them. The children were turned over to the school doctor, the parturient woman to the new midwife, and so forth. What was to be the end of this pollarding of family practice? Were its branches to be scattered about in a wilderness of "specialists," and the family physician a mere sweeper up of inconsidered trifles? But how, the speaker asked, was the practitioner to rise to higher standards of modern science and skill when no means for investigating disease, or of making an intimate diagnosis were provided for him? It was pointed out that the opportunities for tests, analyses, and the necessary examinations which were open to a doctor near a university center should be universal. Moreover, if they were to be fruitful, the practitioner must consult with the scientist. The plants with their staffs should be established in all districts, together with a much larger proportion of cottage hospitals. Cambridge University and its sisters were sending out every year bands of young graduates quite competent to deal with

17. Bloodgood: Article on Binnis Treatise on Regional Surgery, 1917, i, 557.

disease in all its forms, and to use refined means of diagnosis, if these means were supplied. If not supplied, how could they be blamed if they fell into some stagnant routine?

Essentials and Electives in Medicine

There were two most important sectional meetings, one on medical education and the other on medical sociology. The section on medical education was deeply interesting and highly instructive but, as space is limited, the pith of the subjects discussed, as embodied in the following three resolutions handed in at the close of the meeting, will only be given: (1) That the lowest age of registration for the medical student should be seventeen years. (2) That in the forthcoming revision of curriculum promised by the General Medical Council the lightening of professional studies would be facilitated if chemistry and physics were made school subjects, biology remaining a professional subject. (3) That with a view to securing adequate training in physics, chemistry, and biology as applied to medicine, by courses of these subjects within the professional curriculum, it is desirable to exact a knowledge of physics and chemistry of matriculation standard of all medical students before they are registered.

A most illuminating discussion on the future of medical practice took place on July 1, in the Section of Medical Sociology, under the presidency of Sir George Newman, chief medical adviser to the Ministry of Health.

Organize for Community Effort

Sir George Newman[1] opened the discussion by stating that his task was to organize on behalf of the community a profession whose whole tendency is towards individualism; but, as that precious quality—individualism—must not be lost, the "nationalization" of the medical profession was impossible. However, five outstanding problems faced the medical profession in its relation to the state: (1) A new unit of health government must be found. In defining the areas of the Poor Law unions the local sanitary authorities, the insurance committees, and the local war pensions committees the country had been mapped out five times over, but the charting had been done by different hands at different times and for different purposes, causing duplication, overlapping, and confusion. Clearly, there would be advantage in having one authority for all health purposes.

Another common-sense requirement as uniformity of administration in all comparable areas; all through the country there was need for the adoption of accepted standards and a larger measure of equalization and uniformity of central and local action. The plan evolved must represent not what the state alone or medicine alone would prefer, but the will of the people at present—an extension and coordination of medical provision was required. At present there was inadequacy, unequal provision, and piecemeal effort. The provision of medical treatment in the home, at the clinic, in the hospital, and in the convalescent home, not only for the pauper class but for the whole of society, must be brought together in proper relation. A properly connected medical policy would not arrive in their lifetime; all that could be hoped for was to lay some of the foundation stones.

The future of the hospital system constituted another problem with many issues. At present there was no connected hospital system: the relation of hospitals to each other, and to the contributory clinics and the insurance systems, was a typical issue which called for settlement. A fourth subject, and perhaps the most important of all, was an adequate method of education of the undergraduate and the practitioner. A different kind of doctor was needed in these new times: he required in addition to the learning and skill of former days, an improved training in new subjects—in preventive medicine and in the political science of communal responsibility. Some specialization of practice there must be, but it must be recognized that such diseases as tuberculosis, venereal and heart disease would never come under control until and unless the general practitioner was in a position to deal with them. Lastly, the medical man of this new age was concerned with the advancement of humanism. The doctor must be the chief educator of the people in the way of health: in so far that he could not escape his share of responsibility in the study and handling of many of the medicosociological problems, education, recreation, housing, the conditions of industry, sobriety, cleanness of living, the prevalence of venereal disease, prostitution, the penal laws, the causes of certain crimes, the integrity of family life—all such matters concerned all physicians, and to fulfill their vows they must be concerned with them. They could not be wise healers of the patient or of the community without a large sympathy and a liberal humanism. But they must not think that the medical factor was the only or decisive factor; they must interrelate medicine with the social, moral, and ethical movements and aspects of man's mind.

Adequate Attendance for Workmen

Mr. C S. Jenkins expressed the views of the Labor Party and declared that before the adoption of the Insurance Act it was difficult for a workman to get adequate medical attendance: nowadays when the average wage on which he had to support a family was less than £4 ($20) a week, he had very little to spend on the doctor. The Insurance Act did nothing for women and children. The facts as regards industrial hygiene were appalling: in the boot and shoe industry the average age at death was under forty: 90 per cent of the deaths were due to respiratory diseases. In the iron and steel trades the average age at death used to be thirty-nine, but just before the war the figure had improved to forty-nine. Why should man die at this age? The reason was that flesh and blood were cheap. The Labor Party wanted the profession to educate workers in the preservation of their health and to study the conditions under which the workers lived and worked. During the war, when the value of labor was recognized for the first time, the Government set to work to prevent disease and did good work. Why could not this work continue? The Party were not asking for a whole time medical service without a *quid pro quo*: they were willing to give the profession the control asked for and an adequate wage.

The views of all sections of medical practitioners were represented, and also Dr. I. R. Brown, Johns Hopkins Medical School and Hospital, Baltimore, gave the meeting information as to hospital arrangements in the United States.

WESTERN ASSOCIATION OF HOSPITALS

There has been formed in Saskatchewan the Western Canadian Association of Hospitals, with M. M. Seymour, M.B., as president, and Dr. Warren of Calgary as secretary. There will be four vice-presidents for each of the four western provinces.

1. The paper of Sir George Newman will appear in the November issue of MODERN MEDICINE.

ANIMALS SERVE THE PUBLIC HEALTH

The usefulness of animals to man extends far beyond the food, clothing, and other materials which they supply, according to a recent report of studies made by the Bureau of Animal Industry, Department of Agriculture. The following instances in which animal experiments contribute to human health were given in a recent address by E. C. Schroeder, M.D., superintendent of the Experiment Station of that Bureau:

The French abandoned the project of the Panama Canal after a loss of 20,000 lives, but it became possible when animal experimentation revealed the specific nature of yellow fever.

In the development of vaccines, bacterins, and antitoxic serums it has developed safer surgery and surer diagnosis and in this way saved thousands of lives and prevented many more cripples as a result of the recent war. Such diseases as smallpox, Asiatic cholera, bubonic plague, malaria, typhus fever, as well as yellow fever, have been controlled.

In a like manner the Department has been enabled to exclude from this country or to control many food-destroying diseases. Many discoveries useful to stockmen are of service also to hygienists and physicians, and to this source may be attributed the following basic knowledge:

Circulation of the blood; capillary circulation; the vasomotor mechanism; functions of the nervous system; the flow of chyle in the lacteals; the passage of chyle through the lymph ducts into the venous circulation; the nature of the digestive fluids and chemical transformation of food through their action; functions of the liver, lungs, kidneys, and other organs; the reaction of the cells to various kinds of stimuli; significance of the endocrine glands; nature of inflammation and other pathological processes; and numerous other discoveries in physiology, pathology, and biochemistry.

Animal experimentation has also yielded largely to our knowledge of the specific action of drugs. It proved that the manifestations of tuberculosis in different portions of the body all have one essential cause. It proved that tuberculosis is contagious; that the disease is caused by the tubercle bacillus; that the bacillus is quickly destroyed by light but remains alive and virulent a long time in dark places; that there are three types of tubercle bacillus. It led to the discovery of tuberculin, without which, used as a diagnostic agent, the control and eradication of tuberculosis among food producing animals would be impossible.

Experiments with animals have given information that prevents untold suffering of both persons and animals by aiding in the preservation of health and hastening recovery from sickness. Persons who treat diseases among animals probably relieve more pain every day than animal experimentation causes in a score of years.

The foregoing summary of results is believed to be of general interest especially as it relates to the frequent assertion that live stock receives more scientific study than human beings. The fact remains, however, that greater knowledge and skill applied to live stock raising is a definite means of benefiting mankind. For instance, the development of an ample and safe milk supply is obviously a practical way to reduce mortality among and to correct undernourishment of babies. Similarly, the eradication of parasites in sheep is an essential step toward an adequate supply of wool clothing.

In view of the manifold advantages of modern scientific methods for the study of disease, it seems incredible that there should be questioned in any state the right to continue such effective bacteriological, pathological, and physiological experimental work in solving the problems for the welfare of mankind and for their commercial progress.

HEART DISEASE AS A PUBLIC HEALTH PROBLEM

The fact that in patients suffering from heart disease a certain degree of disability often exists for years, and that before death finally occurs there is usually a period of complete disability and dependence which may extend over months or years makes this disease a public health problem of great importance. An accurate judgment of its magnitude is brought out by the figures summarized by Dr. Lewis A. Conner in the *Journal of the American Medical Association* of June 5, who states that among men of military age of the country rejections for organic disease of the heart amounted to 30.74 per thousand. Of those accepted and subsequently rejected at the camps because of heart disease the average was 11.56 per thousand, that is, among 5,000,000 men of military age, more than 200,000 were disqualified because of heart defects.

For civic life figures are not so easy to obtain. During the period of 1915-1918 one of the larger and more carefully managed life insurance companies reported the rate of rejection for heart defects as 24.4 per thousand; this in view of the fact that persons with the more obvious forms of heart disease are not likely to apply for insurance. The Department of Health of the City of New York reports an incidence of heart defects among 250,000 school children of 1.6 per cent, or approximately 20,000 school children with some evidence of such disorder.

The tables of the Prudential Life Insurance Company indicate that diseases of the heart were responsible for almost one-eighth of the deaths of all ages and for almost one-fifth of the death in persons over forty years of age as reported in the United States Registration Area in 1917.

These figures show the affection to be one of the more common chronic diseases, but are not so significant as to single it out for special attention from the standpoint of public health. The present movement for the improvement and coordination of existing agencies for the relief of sufferers from heart disease and for devising measures of prevention has arisen because of the conviction that our present methods of dealing with the problem involve enormous economic waste and immeasurable suffering which is unnecessary and preventable. Dr. Conner summarizes his study with recommendations (1) for the formation of special cardiac dispensary classes; (2) for increased facilities in caring for suitable heart cases in convalescent homes; (3) for greater interest in the welfare of school children with heart defects; (4) for the provision of suitable occupation for those suffering with this handicap.

Efforts for prevention are complex, but must be along three lines which correspond to the three great causes of heart disease: the prevention of rheumatic infection and its complications, the prevention of syphilis and its late effects, and the postponement of the degenerative diseases incident to the later years of life.

Recognition of the importance of the play instinct and of the possibility of using it constructively to make amends for the inroads that industry makes upon personality is destined to lead to a new and more wisely conceived program both in factory and community.—*Ordway Tead.*

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

Otto P. Geier, M. D., *Editor*

INDUSTRIAL REHABILITATION ACT

THE enactment of the law at the close of the last session of Congress which provides "for the promotion of vocational rehabilitation of persons disabled in industry or otherwise, and their return to civil employment," makes possible the repair of injury and the reclamation of the injured on a scale not hitherto attempted and promises a program of conservation limited only by the degree in which it is accepted and the intelligence with which it is administered by the several states. Although the Act has been in effect only since June 2, its provisions have already been accepted in nine states as follows: By previous acts of the legislature in New York, Nevada, Minnesota and West Virginia; by action of the governor, in Tennessee, Arizona, Indiana, North Dakota, and Ohio. It is certain that several other states will soon be added to this list.

The importance of this Act is limited only by the principles and policies carried out in its administration. At best only an estimate can be made of the number of persons disabled each year "in industry and otherwise." The figures on industrial accidents alone indicate that of the 40,000,000 or so people engaged in industry there are about 750,000 who sustain accidents which disable them for a period of more than four weeks' duration and between 15,000 and 18,000 who suffer a permanent disability. Any estimate of the percentage of this number so disabled as to require retraining to overcome the resulting vocational handicap would be only an approximation. Nor are there data from which to ascertain how many of the permanently disabled are unable to return to their former lines of work, as by far the greater number recover entirely from the disabling effects. Not all the changes in lines of work can be charged to the resulting disability and many of the permanently disabled are only slightly handicapped.

In an attempt to arrive at a ratio of industrial fatalities and disabilities in the United States, Charles H. Verrill, of the United States Employees Compensation Commission, found that on the average there are 14,000 persons impaired every year in American industries, to the extent of amputations, the loss of sight of one or both eyes, or 50 per cent or more loss of function of members. If to the "disabled in industry" there are added those requiring rehabilitation because of sickness 200,000 would be a conservative estimate of the number who would come under the provisions of the Act.

The most reliable figures as to the annual yield of disabilities are to be obtained through the industrial boards of the several states; for the statistical year of July 1, 1917 to June 13, 1918, these range from 109 in Utah to 3,000 in New York, the completeness of the record in each case being largely determined by the specifications and requirements of the state labor legislation. The Cleveland survey of cripples in 1915-1916, covering all ages, found the ratio of cripples to be 6 to 1,000 of population, which would yield a figure of 600,000 for the country at large; but this would include some classes not covered by the Rehabilitation Act.

While in the aggregate these totals are appalling and present a reclamation problem of a magnitude not hitherto undertaken, there is to be reckoned to offset the cost of the project the cost to the various communities of the unorganized makeshifts resorted to in the maintenance of their cripples and the economic gain by reclaiming the vast army of those now classified among the "occupationally useless" who require only retraining to endow them with hope and a new earning capacity. The measure is entirely constructive, being directed only toward those capable of retraining. Specific provisions are contained in the law for the formulation of coordinating relationships between state boards of vocational education and the compensation commissions. The first step necessary has been taken. It remains to bring about effective cooperation between state public health agencies, public and private hospitals, the Red Cross, and all social service agencies. Not the least important part of the immediate activity called for is to present the matter to every disabled person whom it is proposed to restore to earning power.

S. P. M.

INDUSTRIAL TOXICOLOGY

THE pioneer stage of industrial medicine is fraught with many a task, according to Dr. William S. Wadsworth in the *New York Medical Journal*, and the most urgent, perhaps the most important problems lie in the field of industrial toxicology. Little help is to be found in the literature, the medicolegal literature lacking the necessary physiological conceptions; the chemical writers spending years in imitating some form of organic substance; and therapeutic writers being too largely concerned with some phase of the subject as developed in a laboratory.

A general toxicological consciousness then is essential on the part of the industrial physician. The lists of poisons given in the textbooks show how completely we have failed to grasp the fundamental nature of poisoning. The poisonous nature of many substances has been strangely overlooked by all writers and many more substances are ignored by most writers. Today almost no one recognizes carbon as the most common and probably the most powerful of all poisons and few consider tin as a practical poison. Our states regulate by law the rela-

tively harmless sewer gas, while little or nothing is done to check the wholesale poisoning by carbon monoxid gas.

Textbooks are full of references to sulphuric acid—and one often hears that the amount of that substance used is a measure of the civilization of a country, but how many point out the fact that most commercial sulphuric acid contains arsenic and that plants and workshops may have a liberal supply of arsenuretted hydrogen to cause a particularly serious type of chronic poisoning that will readily escape the unthinking, unobservant routine follower of the books? One cannot read the literature without being impressed by the frequency of the remark that certain substances are insoluble and therefore are not to be regarded as poisons. This is one of the statements made regarding tin salts, in spite of the fact that dozens of organic salts of tin are quite soluble and do actually cause frightful symptoms and death.

There is no need to worry about how much of a given poison is required to kill or whether it perturbs the heart of the noble frog, but it is essential to get a clear concept of the action of poisons, says Wadsworth. Given a man exposed to and poisoned by a substance the problems of the physician are chiefly along other lines, but all that is possible must be done incidently to master absorption. Above all it is to be remembered that not a few insoluble substances are absorbed. Pretense is to be avoided as to knowledge of what poisons really do in the body except in so far as they show gross results and effects.

An industrial toxicological literature is to be built up on knowledge of conditions, accuracy of observation, alertness to possible explanation, and common sense judgment of values. The physician himself must make a practical study of the problems of the plant, he must learn all substances that enter the factory, follow each substance from its entry to its exit, and must consider well the impurities that may be found in each. Then he must watch the workers along the paths of these chemicals, and especially the new men on the job who have not acquired that tolerance that makes serious chronic poisoning possible.

Difficulties of obstruction in management and inertia or ignorance of the men impede preventive work along these lines. Worst of all, the amelioration of remediable evils often is delayed or made impossible by organized obstruction from vendors of poisons who foist upon the public their deadly stuffs.

A NUTRITION CLASS FOR WORKING CHILDREN IN CHICAGO

By M. J. ROBERTS, M.D., and ANNA BOLLER, Ph.B., Chicago, Ill.

FOR many years we, as a nation, have been combating infant mortality. Instead of permitting nature to make its unerring selection of those most fit to survive, there has been a constant struggle to save the individuals who failed to meet the demands of a harsh environment A generation ago, the high death rate of infants was looked upon as a special dispensation of Providence. Eventually, however, infant mortality statistics produced sufficient alarm to stimulate the adoption of curative measures.

Having accomplished a remarkable reduction in infant death rates, it now becomes necessary to "carry on." The child must not be abandoned to join the vast army of the physically and mentally unfit, and become a burden to society. We need take no pride in a low infant death rate if more persons die from tuberculosis annually than are saved by child hygiene propaganda. The Government has a far greater problem to deal with in furthering the physical welfare of the half grown child than it ever had in dealing with infants. The general tendency in these days of hard work and high pay, is to make the children wage earners at the earliest possible moment.

Problem Is Many Sided

During the spring of 1919 the conference organized by the Children's Bureau at Washington discussed the problem in all its phases—work and play, the family budget, vocational guidance, and labor legislation. The returns from weighing and measuring contests all over the country indicated that malnutrition exists in every age group and in every class of society. The situation is now being met in many ways. Classes and clinics have organized in most of the large cities, and in many states departments of child hygiene are now as active as other departments of state legislatures.

In dealing with working children in Chicago, we consider the Vocational Guidance Bureau of the Board of Education our most valuable agency. It serves as a clearing house for all working children who are below a certain standard of physical fitness. Our beneficent laws permit children, when they have become men and women of fourteen, to earn their own living. They further provide, however, for the inspection and certification of such children until the mature age of sixteen. Physical examination is required in connection with some boards of education, and this is most carefully carried out in the city of Chicago. Those who are applicants for working certificates are not only examined, but their economic status is investigated. Individuals found to have physical defects are aided in every possible way in securing their correction. Free dental and optical work is arranged for in clinics, and all children conspicuously underweight are sent to nutrition classes. The work of the nutrition class is to deal with them in such a way as to make the physical examination prove of actual benefit to the child rather than a benefit to industry by the elimination of the undesirables.

It has never been the special business of any agency to fit children for the wage earning battle in the shop and factory. There are trade schools to prepare their minds and hands for their tasks, but neither the means nor the knowledge has been provided to equip their bodies to combat ill health. Hygiene taught in the average public school is ineffective, the physical training inadequate, and the medical inspection limited to the prevention of epidemics, with the minimum amount of correction of gross physical defects.

In dealing with groups of malnourished or undernourished children the first step is to make each individual aware of his impediments to health, and the next is to help him to help himself. It is a simple matter to tell a child that he has four decayed teeth and to go to the

nearest dentist and have them cared for. It is another matter to tell him that he is twelve pounds underweight and to build up. With many the problem is not what to eat, but where to find the means to be able to eat at all. Nourishing food for a boy of fourteen is a luxury at the present time. If a boy can not work to help out on the family budget there is proportionately less for the family

as a whole to live on and less to eat. The less the child eats, the less fit he is to work.

With such a group, working though undernourished, because of the necessity of adding their bit to the family income, an evening class was organized as a part of the regular industrial clinic at Rush Medical School. The class had the support of the Vocational Guidance Bureau of the Board of Education, from which source all of the children were sent with the understanding that they should follow instructions in order to retain their certificate to work.

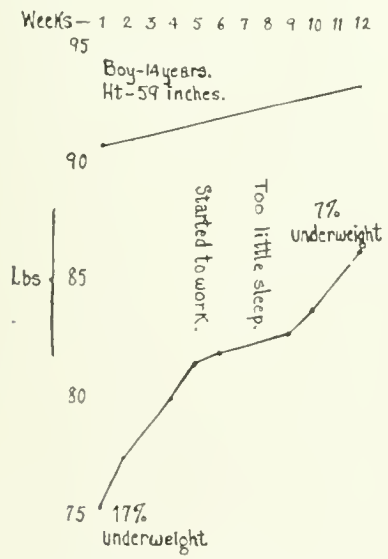

CHART II.—The course of Case 2, 17 per cent under weight, in whom care as to diet and as to the adjustment of rest to his working conditions brought him to normal conditions.

One hundred and thirty-three children made 951 visits during the first eight months of the clinic, which met only once a week; 90 were boys, 43 were girls.

After the first few meetings of the class it was discovered that many of the children came from the office or shop without first going home for their dinner. So it became necessary to furnish something to eat in order that they might be in a proper state of mind to appreciate our talks about three square meals a day. Our only funds consisted of fifteen dollars donated each month by a friend of the clinic. In addition to that the children paid for a very modest supper. The menu always contained some hot dish, bread and butter, jam, jelly, or peanut butter, fresh fruit, and plenty of milk.

We soon found that our suppers were the chief attraction, and the children who could eat at home preferred to join the others at the class. The weekly gain or loss was the main topic of conversation and was the best means we had of stimulating competition. None of the children ever refused milk in any quantity, or to eat potatoes, but their tastes in other respects were decidedly whimsical. After many trials with dishes of all sorts, prepared to demonstrate the foods which we thought the children should eat, we gave up in despair before their refusal to indulge in the experiment. We came to depend upon potatoes as the foundation of the meal. The home diets were so poor that it was not to be wondered at that the very plainest of food was preferred to the

more varied diets to which they had never been accustomed.

On entering the class, each child furnished us with an outline of his regular diet, and these were classified as good, fair, and poor. Of the entire 133, only twelve diets were classed as good; fifty-ninth fair; and the rest poor. Personal hygiene and general physical condition, aside from undernourishment, were investigated on the same basis. In forty-six the general hygiene was good; that is, the teeth were brushed, baths taken at fairly frequent intervals, and the child was sleeping alone in a moderately well ventilated room. In a number of instances the whole family of five or six slept in the same room, and three or four in a bed. In Polish families it was madness to suggest open windows in winter time.

All physical defects were taken into account in the grading of the general condition, the most usual ones, however—such as teeth, tonsils, glandular enlargements, cardiac conditions and posture—forming the basis of comparison. The standardizing of a group, all of whose members were below par, was really a problem. No simple classification, such as good, fair or poor, seemed adequate. The corrective work however, may be given in figures. Fourteen children had their tonsils removed. Every child with bad teeth was instructed to have them taken care of, and practically all of the class have completed their dental repair work, or are still receiving attention. The fact that the children work eight hours

a day makes it exceedingly difficult to secure as creditable records as are secured in class work which permits of unlimited control of corrective work, diet, rest periods, and physical training.

We established a system of rewards which we found to be most efficacious. The children were all conscientious in their desire to gain, but, after a hard day's work in a shop or factory, we felt that the class must offer some special attraction in order to maintain a good attendance record. Each gain in weight was rewarded by a gold star in an individual booklet, and a book full of stars or the final attainment of normal weight for height secured a prize, a fountain pen, book, or knife.

Conquer Crushing Environment

The case reports which follow indicate the results, which, though by no means brilliant, are illustrative of good progress in the face of serious difficulties. The class was specially selected from among the poorest foreign element. Every child was a wage-earner, without a single advantage offered in the way of rest periods or diet, and

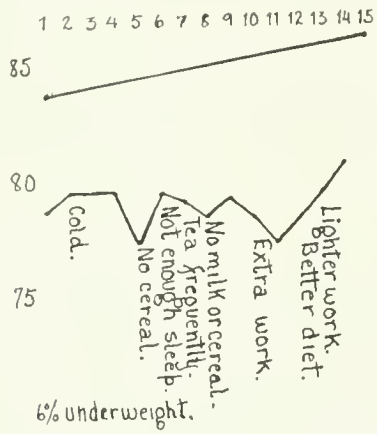

CHART IV.—There is in Case 4 an incipient tuberculosis in connection with a poor diet and other untoward conditions. He is progressively overcoming his handicap.

all the handicaps that it is possible for the stress and strain of modern life to place upon a child. Every gain was entirely due to the individual effort to conquer a crushing environment.

Case 1 is that of a boy of fourteen who was 10 per cent underweight. Physically he was in fairly good condition, except for large, cryptic tonsils. He worked as a type sorter. His diet was fair, but entirely lacking in milk or cereals. This he promptly corrected and gained well for the first two weeks. He then entered the hospital for a tonsillectomy, and remained away from class for a few weeks. On his return he progressed steadily until an illness of a few days duration kept him in bed and caused a temporary loss in weight. His final weight was within two and one-half pounds of his normal weight. He has reached the normal line since the records were reviewed for this paper (Chart I).

Case 2 is that of a boy of fourteen, 17 per cent underweight, who gained rapidly until he began to work, which was about a month after he entered the class. His physical condition was fair, except for a moderately hypertrophied thyroid and a soft systolic heart murmur. His diet lacked milk and cereal, and he drank coffee three times a day. He worked as an errand boy. He promptly corrected his diet and gained rapidly until he started to work, about a month from the time he joined the class. His gain was more gradual for a while and he told us it was because he was too tired to eat when he got home at night. He gradually became adjusted to his working conditions, and made a special effort to get as much rest as possible. He was soon gaining again at the old rate (Chart II).

Case 3 is that of a boy in good condition except for

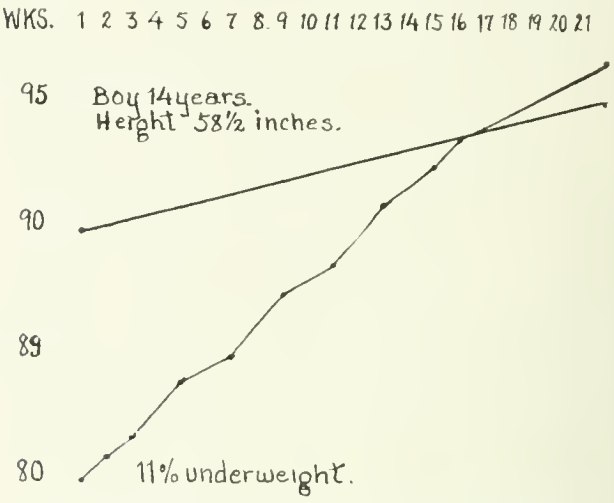

CHART V.—Improved diet and hygiene, together with excellent cooperation, produced the excellent gain shown by the graph of Case 5.

cryptic tonsils. After their removal he gained steadily until there was a sudden loss of a pound and a half during an absence of three weeks from the class. When asked to account for it, he stated that he had done everything wrong, apparently from an experimental point of view to test the effect upon his weight. The experience taught him something apparently, for he continued to improve from that time on with only a few minor setbacks until he reached his normal weight line (Chart III).

Case 4 is that of a boy in whom there were lung findings suggestive of incipient tuberculosis. His diet was poor, and he either would not or could not improve it very much. The notations on the chart indicate the difficulties which prevailed. He has arrived at a point 6 per cent below normal, but will undoubtedly overcome his handicap in time (Chart IV).

Case 5 is that of a boy who worked after school and on

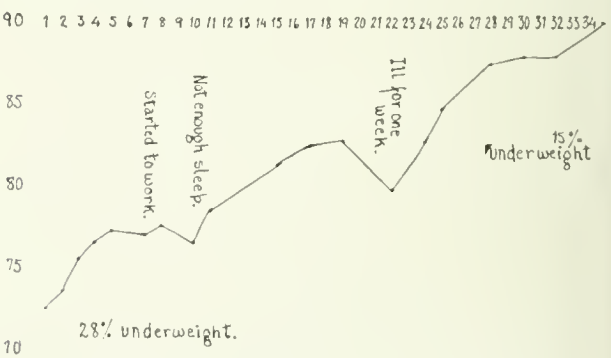

CHART VI.—The graph of Case 6 shows the possibilities of improvement even in the presence of great physical handicaps under the conscientious observance of a corrected regimen.

Saturdays. His physical condition was graded fair, although, aside from his undernourishment, his only defect was extreme dental caries. Improved diet and hygiene, and excellent cooperation produced the result shown (Chart V).

Case 6 is that of a girl 28 per cent underweight. Her

tonsils were moderately hypertrophied, the right lobe of the thyroid enlarged, and she had a left inguinal hernia which was corrected by a properly fitting truss. She had a severe dysmenorrhea, with a consequent anorexia for two or three days each month. She was conscientious, attended class regularly, coming a distance of six or seven miles on the street car. Her normal line is not shown because it was so far above her weight line that shortage of paper would not permit of its being placed within the confines of the chart (Chart VI).

These cases are fairly typical of the general work of the class. The entire class showed an average gain in weight for girls 5.7 pounds, and for boys 6.6 pounds.

HIGH STANDARDS IN HEALTH CARE AT HOTEL McALPIN

By SAMUEL H. MacFARLANE, Hotel McAlpin, New York City.

THE broad interpretation which has of late been placed upon medical services has developed in connection with health activities many phases of welfare work formerly carried on independently, if they were undertaken at all. Any effort to achieve the real welfare of a working body must be twofold: that directed toward the correction or palliation of existing maladies, and the activities which have as their object the supervision and maintenance of conditions conducive to health.

The hospital service in a modern hotel is subject to the requirement of guests as well as of employees. The hospitals provided by the larger hotel corporations conform to the highest standards, and their personnel and organization are nicely adapted to the demands made on them.

The Hotel McAlpin, New York City, has a completely equipped hospital, modern in every respect, in charge of Dr. James A. Harrar, a graduate of the University of Pennsylvania, and Miss Elizabeth P. Harmey who after graduating from the University of Pennsylvania Hospital was for several years chief nurse of the Lying-In Hospital in New York City. Planned as a regular service giving adjunct of the great hotel at the time of its construction eight years ago, the McAlpin Hospital was among the very first to be installed in any hotel in the country, if not in the entire world, and the idea was at once studied and copied by the projectors of other mammoth houses. It is located on the twenty-second floor, very near the top of the lofty McAlpin, where complete quietness is obtained and pure air from mountains and the sea circulates constantly. A modern and completely equipped operating room, with comfortable rest rooms and a suite of reception rooms comprise the hotel hospital. Guests of the hotel are treated in their rooms when ill, and Miss Harmey's staff nurses are assigned to attend them.

Daily clinics for the employees are held at 9 to 10:30 a.m., and 5 to 6 p.m., and first aid is rendered immediately when occasion arises. The work of the physicians and nurses includes the thorough physical examination of every employee, and especially those who come in contact in any way with the food preparation and serving, or even the washing of dishes and laundry department. Although the New York Board of Health requires only one such examination of certain classes of the employees annually the McAlpin management demands that this be repeated every three months.

A Norwegian gentleman who spent a year in this country, for several months of which time he lived at the McAlpin Hotel, and on whom the ever present "flu" had laid a light finger, in a recent letter to Miss Harmey made the following comment:

"The most enjoyable part of my visit to America was the time I was sick in your care at the McAlpin." Although Miss Harmey declares this to be a rather doubtful compliment, she believes him sincere; for he was a good patient, she says, took his medicine regularly, and quickly recovered.

A social worker, who is also a graduate nurse, is employed in this department to visit the homes of the hotel employees, to attend and nurse those who are sick, and to effect a betterment of living conditions wherever possible. That this is no small effort is shown by the fact that on the hotel payroll there are more than two thousand men and women, many of whom are foreign born.

The work of a sanitarian and food chemist in a hotel consists in making tests of samples taken daily of all foods, searching for adulterations and proving food values (*American Press*).

The function of the sanitarian and food chemist, Mrs. M. J. Simmons, working in conjunction with the hospital department, is perhaps entirely unique in American hotel annals. She is a graduate chemist who has specialized in foodstuffs; her work began in Mr. L. M. Boomer's hotels five years ago, creating her own special department at this time. She daily takes samples of all the foodstuffs delivered to the hotel stewards and makes tests, searching constantly for adulterations in the various articles, and proving the butter fat value of the milk and cream.

Mrs. Simmons also looks after the Waldorf-Astoria, Claridge, McAlpin Annex, Woodstock, the Cafe Savarin and the Fifth Avenue Restaurant, of the L. M. Boomer-General Colemand du Pont hotel chain, where her sanitation work includes personal inspection of the kitchens and every space where food of any sort is received, stored, or prepared, as well as the working and living quarters of the employees. In passing, it may be interesting to make mention of the fact that such details as the manicuring of all cooks, waiters, and food handlers are provided for in her program of daily work.

The value of such methods is proved by the fact that during a rigid inspection of the city's hotels and restaurants a few years ago, made by the Department of Health of New York City, the McAlpin hotel won the "white card" for superior excellence in sanitary conditions, it being the only hotel or restaurant to receive such award at the time. "We found measures taken for the sanitary handling and preparation of food and personal care of employees that we did not believe to exist in any institution in the country," read the report of the inspectors on the McAlpin Hotel in the accounts published in the newspapers of the city at that time. The value of such service to an industrial group has been fully demonstrated. The possibilities of the universal application of the principle are unlimited.

INDUSTRIAL MEDICINE AS RELATED TO EFFICIENCY

By JOHN A. TURNER, Ph.G., M.D., Division of Industrial Hygiene and Medicine, Washington, D. C.

THE science of preventive medicine, particularly that branch dealing with industrial sickness and accidents, is receiving at the present time wider consideration, not only from industrial physicians and hygienists, but from the employers of labor, efficiency engineers, labor unions, and a large number of casualty insurance companies. They have all correctly conceived the idea that the efficiency and contentment of workers depend, to an important degree, upon working conditions and on their state of health.

Whether approached from the angle of the interests of the employer or the welfare of the men, a health program in an industrial establishment involves cooperative effort, and presents problems of organization that call out the best purposes and the best talent of all concerned.

All data prove the necessity for such a program. With adequate equipment, the right personnel, and satisfactory relations, the best results in improved health, and efficiency, and in standards of morale are to be achieved.

The best achievement lies in the aroused consciousness of a sense of personal responsibility for health conditions and of the necessity for individual initiative in health practices.

Production naturally is paramount in the minds of employers, as is evidenced by the labor saving machines being invented and perfected; skilled mechanics being employed to keep them in repair and operating to the maximum, while other experts are employed to increase production through the workers by such methods as speeding up, rearranging machinery, obliterating unnecessary motion; but at the same time they neglect a most vital point, "the wear and tear of the human machine." This oversight no doubt is accounted for by the fact that only a medical man, with his knowledge of the human mechanism, can keep the body to a health standard.

It, therefore, being the physician's duty to maintain the health of workers to the maximum standard in order to be successful in his work he must convince the employer that the medical department is of vastly more importance than it has in the past been given credit for. In many instances the medical departments have been handicapped by being under the management of the labor, safety, or production departments, when it should be an independent department. The physician's services are of equal importance to those of the attorneys, yet in few instances is the doctor considered as on a par with him or with members of the plant staff.

Research in Preventive Medicine

The function of the industrial physician is not merely to care for the injured employees, but to prevent injuries and sickness, and to maintain the physical status of the workers to a maximum standard. Although to bring health back to a severely injured man is more attractive and picturesque, yet the homely process of prevention is more essential. In this branch of preventive medicine the physician will find a field in which he can do considerable research work, and one in which he will discover that a vast amount of human waste is the result of having been satisfied merely to care for the wreckage.

In this connection there is also to be considered the economic side of the question previously mentioned in terms of the efficiency of workers, which to an important degree depends upon their health. Maintaining their health to the maximum standard will markedly (1) increase the quality of production; (2) increase the quantity of production; (3) increase contentment, morale, and loyalty; (4) decrease the frequency and severity rates of industrial and non-industrial accidents; (5) decrease the frequency and severity rates of industrial and non-industrial sickness; (6) reduce the absenteeism rates; and (7) reduce the labor turnover rates.

It is through the efficient efforts of the medical service that the above results are to be obtained. A physician doing industrial work, especially that part pertaining to prevention, must first of all consider what he has to work with, that is, the suite of rooms, their location, equipment, and the personnel.

The dispensary, or the suite of rooms used for this purpose, should be located centrally or near the gate, so as to be easily accessible to all departments of the plant. To house the employment department in the same building has this advantage,—an applicant can without delay be taken to the dispensary for his physical examination. The number of rooms for the dispensary will depend upon the amount of work performed; an ideal, or, what may be considered the necessary number of rooms, should consist of a reception room, doctor's office, drug room, surgery, dressing room, clerks' room, ward, toilets, and storeroom.

The reception room should be of sufficient size to accommodate all the patients; it should be equipped with chairs and table. The surgery should be equipped with operating, treating, and instrument tables, cabinets, and all necessary instruments. The appliances should be sufficient to care for even major injuries. The surgical dressing room is a most essential room, as it is where the peak load of the work will be done. The drug room should be well stocked and maintained to standard. Drugs for the relief of trivial illnesses should form an important item. The room for the clerks should be supplied with desks, typewriter, filing cabinets, and all necessary materials. The ward should have partitions to allow segregation of the sexes, provided both are employed. All rooms should have an abundance of both natural and artificial ventilation and illumination. They should be free from noise.

Personnel—the Choice of Physician

The physician should have the privilege of selecting his assistants, as the success of his work will depend largely upon the character, training, and experience of his aides. Nurses are essential to every dispensary. One should have charge of the dressing room and surgery. In a number of plants it has been found advantageous to employ a nurse solely for the purpose of looking up all absentees. After a given waiting period the nurse will call at the home of the employee to ascertain the cause of his absence. If absence is due to sickness, or to caring for a sick member of the family, the nurse will give such assistance and advice as are in her power, and if, because of financial conditions, they are not receiving adequate care, she will communicate with the chief surgeon, when he or an assistant visits the home and takes full charge of the case.

This phase of the work is far reaching in its effects,

chief of which is the effect it has upon the employees. They learn that the employer is interested not only in their welfare while working, but in their home conditions as well. If an employee comes to work knowing his wife or other member of the family is sick, he is bound to worry; on the other hand, if he knows that they are receiving proper medical attention, his mental attitude will be more alert and he can more easily concentrate on his work in a way he otherwise could not do. In a plant where women are employed it is advisable to have a middle aged nurse, one who is endowed with tact and good judgment, in order that she may assist and advise them in personal hygiene. Clerks in the dispensary are necessary to round out the personnel, at least one of whom should be a good typist who is also familiar with filing and cross-indexing.

Medical Service on a Business Basis

Having the dispensary, equipment and personnel, the physician should proceed to place his department upon a business basis and on a par with other departments in the plant by showing at the end of the year a profit in dollars and cents. The first step in placing the service upon a solid foundation is to take an accurate invoice of the plant, that is, a record, in the minutest detail, of the physical condition of the employees and the conditions under which they labor; also, an accurate record of the medical department itself, including rent, heat, light, equipment, supplies, salaries, and all other expenses. It should be his next concern to compute the frequency and severity rates of accidents and sickness for the preceding year, to make an estimate of the cost to the employer and to the employees. This will give a clear picture of the cost for the past year, and comparison with the following year's report will show the loss or gain that has been made.

There are many factors which an industrial physician must consider as causes for lowered efficiency: those directly related to the health of workers may be classified as follows:

Factors Contributing to Accidents

(1) Lack of or inadequate mechanical safety devices. (2) Inadequate illumination, natural and artificial. (3) Condition of machinery. (4) Condition of floors, slippery or uneven. (5) Falling objects. (6) Inadequate ventilation, natural and artificial. (7) Mental and physical condition of workers. (8) Carelessness. (9) Lack of familiarity with work. (10) Lack of instruction in accident prevention.

Causes of Occupational Disease

(1) Dust: vegetable, mineral and metallic. (2) Poisons: organic and inorganic. (3) Fumes. (4) Gases. (5) Smoke. (6) Infectious materials: hides, meats, cutting compounds, etc. (7) Inadequate ventilation, artificial and natural. (8) Lack of protective clothing. (9) Lack of shower baths. (10) Lack of washing facilities. (11) Toilets, accessibility and condition. (12) Inadequate illumination, natural and artificial. (13) Excessive variation in temperature. (14) Humidity. (15) Eating in work rooms.

Non-Industrial Health Conditions

(1) Lack of knowledge in personal hygiene. (2) Improper clothing. (3) Contact with employees suffering from infectious or contagious diseases. (4) Absence of sputum receptacles. (5) Promiscuous spitting. (6) Contaminated water and insufficient supply of palatable water. (7) Inadequate housing conditions. (8) Lack of personal service facilities, or because those present are uninviting and insanitary. (9) Common drinking cups. (10) Common towels. (11) Habits such as alcohol, tobacco, drugs, and over-eating. (12) Improper food. (13) Lack of prophylactic measures against such diseases as typhoid, paratyphoid, and small-pox. (14) Lack of dental service.

Absenteeism and Labor Turnover Rates

(1) Accidents, industrial and non-industrial. (2) Sickness, industrial and non-industrial. (3) Lack of or inadequate personal service facilities. (4) Unsympathetic supervision. (5) Lack of or inadequate medical and surgical relief. (6) Dissatisfaction with wage scale. (7) Housing conditions. (8) Lack of welfare work. (9) Fatigue due to heavy work, overtime, speeding up, lost motion, etc. (10) Physical and mental status of workers. (11) Workers laboring at tasks which they are physically and mentally unfitted to perform.

Take Stock of Physical Assets

In order to invoice the manpower of a plant a careful physical examination needs to be made of each employee, this for the purpose of fitting them to work which they can perform effectively without further impairment of health; also, to correct in so far as possible the defects that exist. Subsequent examinations should be made at regular periods to ascertain the effects of the work upon their health. Those whose occupation is known to be hazardous should be examined at least once a month. Whenever the output of an employee begins to fall off, he should be examnied to determine if it is due to the work. Upon returning after an absence on account of an accident or sickness, an employee should be examined to determine his fitness for resuming work, as lowered physical tone would make him susceptible to subsequent accident. Food handlers should be examined frequently to guard against transmissible diseases. At the outbreak of an epidemic all employees should be inspected daily, for by this means the dissemination of contagious diseases can be kept to the minimum.

Physical and Temperamental Requirements

The physician should thoroughly study the various processes in his establishment and determine the physical and temperamental requirements of each, so that he can intelligently advise in the placement and transfer of the workers. In determining the standards for the various occupations the physician should keep in mind that there are tasks which cripples may successfully perform as this will help to solve the problem of how best to care for the vast number of industrial cripples who might otherwise be discarded: for example, if a man with one arm should present himself at the employment office, the doctor and the employment officer should know what tasks a one arm man can perform. The recent work of the Federal Board for Vocational Education in re-educating and rehabilitating crippled soldiers and sailors, has proved the value of adopting this work for industrial cripples.

Cooperation with Other Departments

A closer cooperation between the medical, employment and safety departments will result in mutual benefits. The physician should give the foreman instructions in accident prevention, in the recognition of the early symptoms of industrial poisons, and as to the best methods of rendering first aid in emergencies. It should also be the function of the foreman to fill out accident reports on all accidents. The routine of this work would keep him on the lookout to prevent future accidents.

The medical department should furnish departmental

heads with a monthly summary report, tabulated by occupations and departments; such a report would no doubt create a rivalry between departments and result in a decrease of accidents, sickness, and absences due to other causes. A copy of the report sent to the safety man would indicate to him the departments requiring his special attention.

Industrial and Non-Industrial Sickness

Industrial and non-industrial sickness plays a very important rôle in the high absenteeism rates and the cost of production. In many instances there is a close relation between accidents and the health status of workers.

That sickness is one of the vital factors causing loss of time is readily seen from this simple statement[1] of the situation: "Summarizing the results of a number of investigations made into the sickness prevalence and its severity in the United States, an average annual loss of working time is reported, for wage earners over 16 years of age, of 6.9 days. With about 40,000,000 wage earners in this country, such a sickness would approximate 276,000,000 working days, or a loss of about 1,000,000 wage earners. This means a wage loss only and does not take into consideration those losses through slowing up of the process, which depends upon the continuous performance of skilled labor, nor the overhead charges of supervision and operations which continue whether or not the workers are present." Nor does it include the loss in efficiency of those who continue to labor while in a physical condition below par and until they are compelled to quit.

Another report[2] shows a still higher rate, the source of data being the records of sick leave of Government clerks in Washington, D. C., 1914: census of population, 16,000; the number of days lost per person, per year of 300 days average 4.8 days. Sickness surveys in various localities by the Metropolitan Insurance Company, 1915 to 1917, census of population, 376,573, the average loss of time being 6.9 days per person per year of 300 days. The New York City Health Department illness census of health district No. 1, 1916: census of population of 20,169 gave an average loss of 8.2 days per person, per year of 300 days. The United States Public Health Service sickness survey of seven textile industries in South Carolina in 1916, with census of population of 2,367 gave an average loss of 17.6 days. The total number of people covered by this report was 415,109; the average number of days lost per person per year of 300 days for this number was 8.6. Reports of this nature obviously points to the facts that industrial physicians have before them a big field of work, for industrial diseases can be eliminated and non-industrial sickness can be reduced even to the extent of 25 per cent. This is a conservative estimate and should prove beyond question the importance of preventive medicine and its effects upon the productivity of factory workers.

Factory Inspections Necessary

In order that the physician may obtain the necessary information relative to the health of the workers and the conditions under which they labor he should make regular and systematic inspections of the factory grounds, buildings, and processes, in making which inspections the following points are to be considered in detail:

Illumination.—Natural illumination is always the best light to work with. Three important points are to be considered: (1) The amount of light admitted through windows, skylights, and open doors; (2) the situation of the work planes in relation to the light areas so as to obtain the maximum without subjecting the workers to direct glare of the sun; (3) the presence of any obstructions, internal or external, which might interfere with an even distribution of light.

It is estimated[3] "that a ratio of illuminating to floor area of one to four or five is adequate for work of a fine character in factories and one to seven, or, one to ten for office buildings." This is true, provided there are no obstructions and the light is evenly distributed to the working planes.

Artificial illumination is necessary in buildings in which the natural illumination can not be had, and for dark days and night work. The essential points to be considered are: (1) the location, number, and intensity of the globes; (2) the protection from glare by such means as reflectors, frosted globes, and the distance from the work planes. That illumination plays an important part in the quality and quantity of production is shown by the following report of the Departmental Committee on Lighting in Factories and Work Shops.[4] In one instance the output of a factory was diminished from 12 to 20 per cent during the hours of artificial lighting; and in another factory the earnings of the workers increased 11.4 per cent after the installation of a better system of lighting.

Ventilation.—Over-crowding, fortunately, is rare; for in most factories the character of the work does not require a sufficient number of workers to make over-crowding a hazard. It is now an accepted fact that the evil effects of crowding of many human beings into confined spaces is due to the increase in temperature and the humidity of the air, and that in such an environment there is decreased physical and mental capacity for work.

The natural ventilation of factories is provided by means of windows, skylights, monitor roofs, and open doors. During the summer months these are likely to be sufficient, but during the winter months, when they are often closed, is the time for the physician to pay particular attention to the natural means of ventilation.

Artificial ventilation is required when the natural means are inadequate and in the presence of excessive heat, poisonous fumes, gases, smoke, and dusts. If the plant has no exhaust system, one should be installed and frequent inspections should be made to ascertain if it is operating properly.

Personal Service Facilities

In making inspections the physician should ever keep in mind the personal service facilities and their relation to the health and comfort of the workers. The location and sanitary conditions of the toilets are of utmost importance—the location, because if placed at a distance and inaccessible, the workers are liable to put off calls of nature, especially to be noted among workers on a piece basis. Insanitary conditions of toilet rooms, such as improper ventilation, light, heat, or a dirty or dilapidated condition, will cause the workers to avoid them, thus inducing chronic constipation, with its many sequelae.

A sufficient quantity of good drinking water is also essential to health, and here, too, the location is important. Sanitary drinking fountains of an approved type should be in every department; samples of the water supply should be taken at regular intervals and subjected to a bacteriological examination in order to prevent an outbreak of water borne diseases.

3. Scherewsky, J. W., M.D., United States Public Health Service, Bulletin No. 71, p. 106.
4. Departmental Committee on Lighting in Factories and Workshops, London, 1915.

Each department should have a well equipped wash room, with a sufficient number of bowls, a plentiful supply of hot and cold water, soap in the form of liquid or powder, in sanitary containers, and paper towels. The workers should be instructed to wash their hands and faces before eating, after visiting the toilets, and at the end of the work period. Not only are communicable diseases disseminated by means of the hands, but large quantities of dirt, dust, and poisons are liable to be ingested.

A locker room and lockers of an approved sanitary type should be in each department. It might be desirable to have them in the wash room, provided the room is of sufficient size; otherwise a room adjacent to the wash room may be provided.

A room equipped with showers should be adjacent to the locker room. Showers are not luxuries, but are necessary to keep the workers in a healthy condition. Those who work with dirty materials and those who handle infectious or poisonous materials should be required to take a shower before going home. The shower room should be properly ventilated, heated, and lighted.

Rest rooms, although they are not absolutely necessary in all plants, will go far toward increasing the comfort and contentment of the workers. These rooms should be plainly but tastefully furnished and current magazines should be supplied. In some plants a circulating library has proved of value. Technical and reference books on the particular industry should be available for those who are desirous of enhancing their knowledge in their particular occupation.

A restaurant or lunch room should be in every plant; the food should be of good quality and supplied at cost. In plants where it would not pay to conduct a restaurant, a lunch room should be supplied with tables and chairs and a stove where food and coffee can be warmed, an arrangement which will be especially appreciated during the winter months. It is a hard sight to see employees seeking corners and working material in the work room where they may sit down to eat cold lunches with the added discomfort of the lack of proper facilities for cleanliness.

Education in Personal Hygiene

The plant physician is performing only a small part of his duties if he neglects to instruct the employees in personal hygiene. It is through a systematic course of this nature that the physician will obtain his best results in sickness prevention. Wage earners are just as anxious to prolong their lives as other people, and it is only through lack of knowledge that they fail to observe the hygienic laws.

WORKING OUTPUT

By OUR LONDON CORRESPONDENT.

WHILE preventive medicine is rapidly coming into its own, no branch of it is receiving closer attention or making more rapid progress than that of industrial medicine. It is curious, but true, that although in Great Britain the industrial revolution had its inception and that in this country the care of the public health was founded on scientific lines and developed, the scientific study of the law governing the healthy employment of the human mind and body was strangely late in its development. Up to quite recent years the question has been considered almost wholly from political and charitable viewpoints and no appeal has been made from the scientific aspect, to the laws of physiology, or the test of experiment, which might have shown then as they have shown since that a reduction of hours would have increased industrial output no less than health and human happiness.

However, the stern experience of war with its demands for strenuous and long maintained industrial effort drove home with unerring force the British national lack of knowledge of the elementary and fundamental laws governing human efficiency, and, especially the need for systematic and scientific study of the hours of work, the arrangement of spells of work, and other conditions of labor best calculated to produce the maximum output. Since the beginning of the war the scientific investigators of Great Britain have done a great deal of valuable spade work in this direction. It has been demonstrated conclusively that long hours of monotonous labor are not conducive to large output, good health, or contentment. The first annual report of the British Industrial Fatigue Research Board has been issued recently and naturally provides some very instructive and interesting reading. The Research Board was appointed in July, 1918, by the Medical Research Committee and the Department of Scientific and Industrial Research jointly with the following terms of reference:

"To consider and investigate the relations of the hours of labor and of other conditions of employment, including methods of work, to the production of fatigue, having regard both to industrial efficiency and to the preservation of health among the workers." The Board, which was composed of some of the most eminent scientific investigators and practical men of the country, recognized at the outset that the problem of industrial fatigue could only be successfully attacked by two simultaneous lines of research, the one medical and the other industrial, and they formulated their plan of campaign in accordance with these views. Since the formation of the Board twenty investigations in all have been sanctioned; of these four have been completed and the results published, two and part of a third have been abandoned, nine are now proceeding, and six have not been yet begun.

The most interesting report issued was that of the iron-founding industry. The inquiry was made by Dr. C. S. Myers and the results were published in June, 1919, in Report No. 3, by "A Study of Improved Methods in an Iron Foundry." The report, which indicates the large increase in output following the introduction of scientific methods, caused much interest both in this country and in America. In March, 1919, an investigation having for its object the determination of a reliable test for fatigue was entrusted to Mr. Muscio. After attempts extending over several months, Mr. Muscio reported that he had been unsuccessful and that owing to the impossibility of eliminating will in the subject, there was little probability of devising such a test suitable for practical application. It may be mentioned that part of the investigations were abandoned in the absence of any known reliable test for fatigue. Efforts, however, are still being made to discover such a test and, if these are successful, it is proposed to revive this part of the investigation at a later date. The Board has now resolved to discontinue the inquiry with regard to a satisfactory psychological test for fatigue and to proceed upon physiological lines, which seem to offer a more hopeful prospect. An offer from Mr. B. A. McSwiney, M.B., lecturer in physiology at Leeds University, to undertake research of this subject has been accepted and, as a beginning, arrangements have been made to study the possibility of using the wink reflex and changes in the pulse rate as media for a satisfactory fatigue test.

The work of such a Board is necessarily slow, but already some valuable facts in relation to output and

health have been discovered. It has been shown that short hours of work, especially in some trades, increase output and improve health—which means much the same thing; for if the body and mind are not in a healthy condition and work in unison, output must deteriorate in quality and decrease in quantity. Particularly has it been proved that monotonous toil is detrimental and very producive of a spirit of unrest. Investigations as to industrial fatigue prosecuted here and in America can do nothing but good. There is no doubt that scientific industrial and medical research should be encouraged in every civilized country.

MEDICAL GUIDANCE IN INDUSTRY

Medicine in its proper relation to industry is very ably discussed by S. Dana Hubbard, M.D., in the *New York Medical Journal* of August 14, 1920. Problems of management are thoroughly canvassed and the several functions of the industrial medical officer are fully outlined. There is no use talking in highbrow phrases and neglecting essentials, he says, and the efficacy of the service will depend upon educating the workmen as to what are the prolific causes of both sickness and accident. He emphasizes the need of a comprehensive medical service in industry by the following statements of correlating facts:

There are about forty million people engaged in industry. Of this army of workmen there are about 750,000 who sustain accidents which disable them for a period of more than four weeks' duration. There are about 22,500 industrial workers killed annually, and between 15,000 and 18,000 who suffer permanent disability. The economic waste from these accidents means the loss of working time of over 60,000 laborers, or 18,000,000 work days a year.

Sickness in industry likewise exacts a heavy toll. We are informed from the same source that the average worker loses about nine days a year. This means a loss of one million workers a year, or 360,000,000 days a year, both of which, estimated at an average per diem wage, means a stupendous amount in dollars and cents. This is the loss simply from sickness and accident; to this must be added the loss of production, the cost of medical and nursing service and medical supplies, and sundry expenses, which make a sum running into the billions. There is no greater problem before the country today than that of caring for the industrial worker, and there is no one in this country who can better cope with this situation than the properly trained and equipped industrial physician.

CANADIAN COMMITTEE ON INDUSTRIAL FATIGUE

A committee on Industrial Fatigue, under the honorary Advisory Council for Scientific and Industrial Research, has recently been established by the Canadian Government. The functions of this Committee are purely advisory and investigatory. Its general purpose is to make the knowledge and experience of medical science, as it bears on industrial health and efficiency, available for all industry.

The main objects of the Committee are: (1) to offer manufacturers the assistance of scientific laboratories in solving the health problems presented by particular processes in their plants; (2) to offer all interested the use of the Committee's intelligence bureau, where the most up-to-date information on general and specific problems of industrial hygiene is kept; (3) to cooperate in investigations into the conditions in different industries; into the incidence and causes of sickness, whether occupational or general; and into the actual relation existing between hours of work, working environment, etc., and production.

The Committee is composed of professors from the University of Toronto, Laval University, McGill University, and Dalhousie University, and representatives of the women's organizations, the Department of Labor, and one representative of industry. An office has been established in the Medical Building of the University of Toronto. The Committee plans later to establish offices in the chief industrial centers of Canada.

FEES ON GRADUATED INCOME BASIS

There is reported in *The Lancet* of July 3, 1920, an important experiment in providing a complete medical service for the staff and work people of a London, England business house. The experiment was inaugurated on a small scale some time ago by Messrs. Thomas de La Rue & Co., Ltd., and has met with such success at their hands that the company is now commending it to other employers.

The kernel of the matter is that a number of consulting physicians and surgeons have agreed to treat privately at reduced fees patients sent to them by the company, the fees to be based upon what is described as "adjusted income." This includes private means as well as salary, one-fifth of the total being deducted on account of each child or other dependent member of the household. The fees payable vary from 10 to 60 per cent of the norm for operations and from 25 to 100 per cent in the case of consultations and medical treatment, a minimum of a guinea for a single visit being payable in all cases. In order to insure that cases are not sent to the consultant staff without due cause, a certificate is required in each case from the company's medical adviser, the patient then going on to the consultant with a voucher stating the proportion of the normal medical fee payable by him. The company thus constitutes itself as almoner to private practice, relieving the consultant of the onus of making tiresome inquiries.

A further proposal is now made with a view to the provision of a great central nursing home for the reception of employees from a number of business houses at reduced fees, it being suggested that a private institution of this kind with a large number of beds could be run at considerable less expense than at present prevails in the smaller nursing homes now available. Mr. Stuart de La Rue states that his scheme has so far received the whole-hearted support of the medical profession.

PROTECT WORKERS IN COMPRESSED AIR

The German Minister of Labor has decreed that medical supervision of the health of all persons working in compressed air is compulsory. If the pressure is over 1.3 kg. per square centimeter, the physician must live near the place where the work is being done and be accessible at all times. With a pressure of 2.5 kg. the continuous presence of the physician is imperative. Men under twenty and over fifty must be excluded from compressed air work.

Many a good judge would be hurtful if he did not get through newspapers and magazines a diluted kind of sociology which saves him from bondage to mere precedent.—*Ross.*

THE MEDICAL DEPARTMENT OF THE FULTON BAG AND COTTON MILLS

By D. T. HEYSER, M.D., Director of Medical Service, Atlanta, Ga.

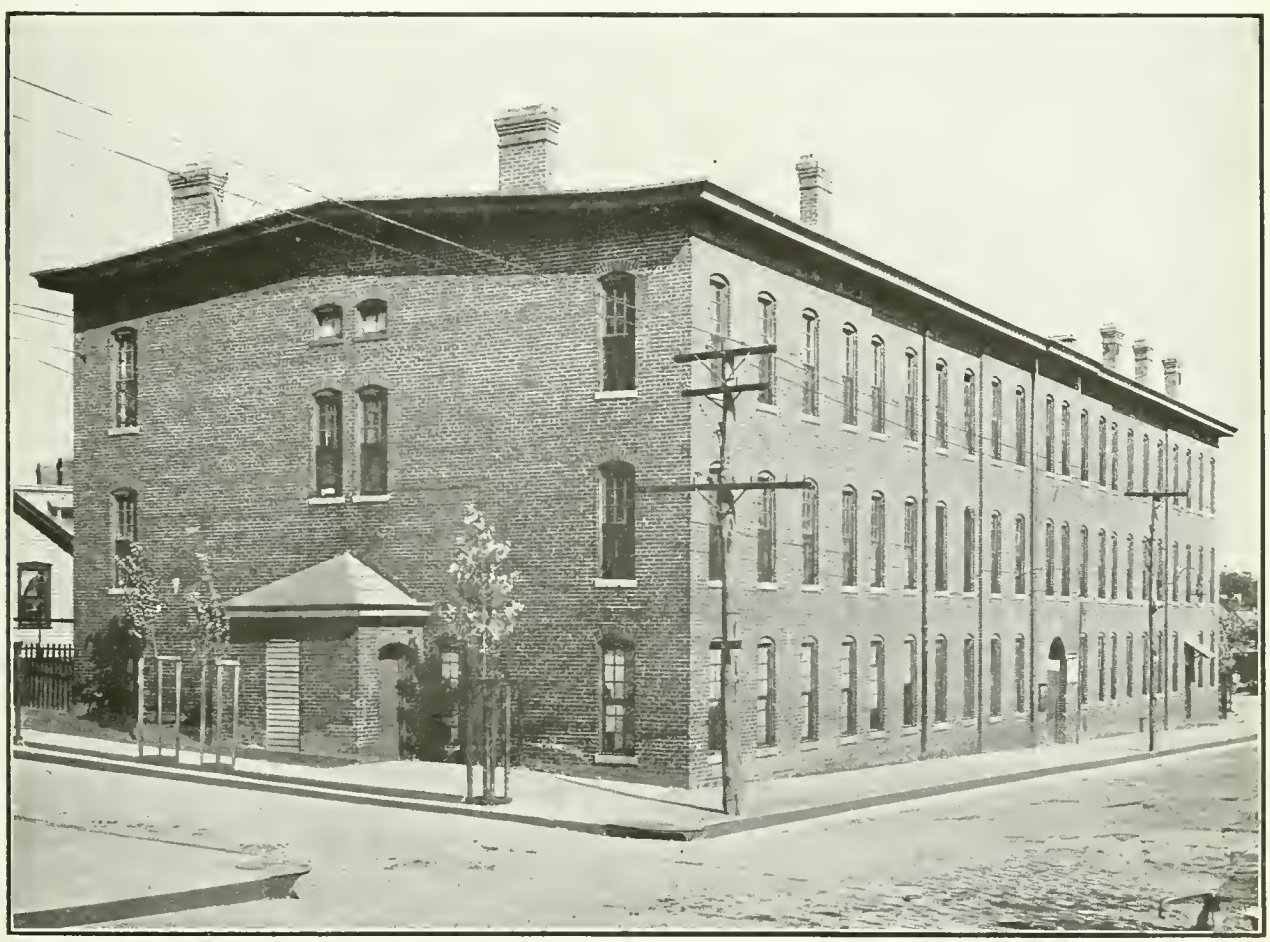
IN THE past few years the attention of manufacturers has been directed as never before to the human factor in industry—to its recruiting, to its maintenance, to its conservation. Corporations recognize today that the health of employees is one of their first considerations both for humanitarian and for good business reasons, arguing on the hypothesis that a well man does his work well while a sick man does his but ill. With this as a starting point the medical work mentioned and developed by manufacturers has assumed a status of national importance and a public health work of the highest order, carrying out the spirit of the proverb that "an ounce of prevention is worth a pound of cure."

The Medical Department of Fulton Bag & Cotton Mills, of Atlanta, has been developed steadily and consistently in response to the need of our employees, until today it is ministering not only to its two thousand employees, but to the wives and families of employees as well.

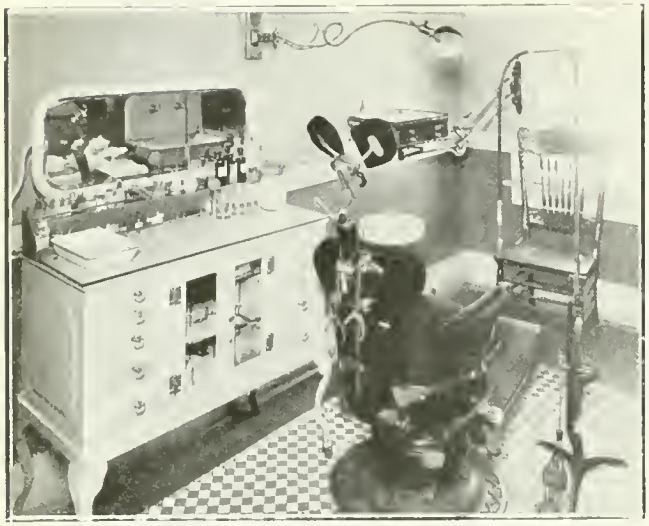
In order to maintain an adequate medical department, a suite of rooms has been set aside in the Fulton Club House, separated physically from the other activities of the Service Department, but working in close cooperation with all departments and their members.

At the head of the medical work there is a full time physician, resident in the medical suite and subject to call at any time, who visits the sick employees or any member of the family in the home, and in addition has regular office hours in two different offices in the plant in order to reach a larger number of patients. The fact of residence makes him an important influence, for employees understand that his services are available at any time.

On the staff of the hospital there are three trained nurses, two of whom devote a large part of their time to visits in the home of employees, the list of absent employees being sent to the medical department early each morning by the employment manager. These visiting nurses do bedside nursing, give instruction in home and personal hygiene, work in connection with the educational department to keep children in school, and report to the doctor daily such employees as they find in need of his attention. The resident nurse has charge of the dispensary, giving out drugs as called for by the doctor's prescription; she also attends to minor accident cases, redressings and other hospital duties as the head nurse as directed by the physician in charge.



The Fulton Club Building wherein are located the hospital, dental, and medical departments. It contains a cafeteria, and gymnasium which provides facilities for indoor games. Here also are conducted a night school and kindergarten instruction classes.



The dental department is open every day in the week except Saturday. Treatment is given at the bare cost of the service.

A small first aid hospital is one of the first requirements of an industrial medical department, and a majority of plants stop at this point. In addition to this room however, there are in the Fulton Hospital two small wards of a three bed capacity each, in which are cared for the more serious accident cases, acute non-contagious illnesses, and confinement cases either of employees or members of their families.

In addition to the full time staff of medical workers the company employs a dentist who gives two and a half hours daily except Saturday to the care of the teeth. The number of patients runs gratifyingly large—200 patients monthly, or about 10 per cent of the total number employed. The dentist also instructs his patients in oral hygiene and prophylaxis.

Both visiting nurses conduct nutrition classes once each week—each class numbering twenty boys and girls who are suffering from malnutrition. These children respond readily to right feeding and build up rapidly as a result of following out the prescribed diet. As each one "graduates" his place is filled by a child on the waiting list.

A semi-monthly nasopharynegeal clinic conducted by a visiting specialist has met with excellent response and marked success. The fee charged in each case is nominal, and the four to six operations monthly are largely tonsil and adenoid removals. Other operations are done when necessary. Many children especially benefit by this clinic.

For the babies there is a regular weekly clinic under the auspices of a baby specialist. There is also a visiting physician who regulates the diets and gives advice and treatment as necessary. His services are free to all wives of employees and women employees who have children.

Mothers who must work may bring their children to the day nursery where for the very small fee of five cents per day they are cared for all day. Each child must be examined by the doctor upon admission, and the doctor and nurse see the children daily. A special room is maintained for prompt segregation of any ailing child to prevent danger of infection. Drills in hygiene are given the children at regular intervals by doctor and nurses, and the children are taught something of the proper physical care of themselves.

The nurses give much attention to prenatal work—instruction as to living, food, exercise, etc.—and they care for the mother at confinement if she comes to the company hospital; if, however, she refuses to do so, she must provide her own physician. This is, of course, to insure proper sanitary surroundings and treatment, and to guard against well meant but often deadly intervention of family and friends.

The dispensary carries a complete line of the requisite drugs. These are supplied on prescription to employees at cost.

A treatment and clinic room is provided for the separate handling of chronic illnesses, such disorders receiving the regular care of an experienced house physician.

An important phase of the medical work is with persons with venereal disease, both men and women. Such patients are treated at the hospital clinic, and given printed instructions how to care for themselves as well as how to prevent infecting others. Results here are slow, of course, but are increasingly good.

The number of cases treated shows more convincingly the scope of the work. The number of office visits to the doctor average five hundred monthly, while the total number of patients for the month in all phases of the medical work is about one thousand six hundred.

We do not feel that we have attained our goal, however, with the work even at this stage of growth. As the overcrowding of our facilities demands, we expect to enlarge various phases of our activities and add others, feeling assured of the permanent value of the medical department and its ideal of service to the persons with whom we have our daily intercourse.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

PUBLIC HEALTH EDUCATION AND THE LAMAR BEQUEST

It will be remembered that a generous sum of money, reported to total about ten millions of dollars, was left under the Lamar will to the medical schools of Harvard, Johns Hopkins, and Columbia, to be devoted to the furtherance of the cause of Public Health. The will was so worded as to make no sharp distinction between the intimately related fields of medicine and public health, and the bulk of the endowment is available for the building up of fundamental medical departments such as bacteriology and physiological chemistry. The testator did, however, specifically provide that a portion of the fund should be utilized for the dissemination of knowledge to the public in regard to the science and art of healthy living; and the plans of the three universities for complying with this requirement are of special interest.

Harvard, as we understand, is planning to fulfill the Lamar bequest by an expansion of the admirable system of public lectures on medical and hygienic topics, which have for some years constituted a feature of the scientific life of Boston. Johns Hopkins has annonnced the establishment of a new technical journal, the *American Journal of Hygiene,* which under the editorship of Dr. Welch will be of the greatest value as a medium for the publication of important original contributions to the subject. Such an organ, which will fill the place of the English *Journal of Hygiene,* has long been needed in this country since the *American Journal of Public Health* cannot well handle long and technical contributions, and the *Journal of Bacteriology* and other organs in allied fields are overcrowded. Finally, Columbia has developed a third distinct line of service by appointing Dr. Haven Emerson director of a Lamar Bureau of Public Health Information, which will supply accurate and complete data in regard to current public health practice, particularly to the medical and nursing professions and to the public health worker himself.

It will be noted that neither of these plans contemplates an attempt to deal directly with the exceedingly difficult problem of educating the "ultimate consumer" of public health science, the average citizen, who must make its final application in his or her daily life. It is of great importance that the teacher should be taught, and the work to be undertaken at Harvard, Hopkins, and Columbia under the Lamar bequest will fill important gaps in the general scheme of public health education. It is clear, however, that the time is coming when we must pay more serious attention to the technic of public health propaganda as applied to the education of the general public. How far are the efforts devoted to lectures and exhibits, to circulars and monthly bulletins, to newspaper articles, to "Baby Specials," and "Health Cars" really effective? Do they catch the attention of the individuals they are designed to reach? Do they teach a lesson so clearly that it can be grasped by the majority of those who hear it? Do they produce an impulse to a change in conduct which will cause the intellectual concept which has been imparted to bear fruit in good works?

We do not know the answer to these questions. In the past, we have never attempted even to study them by the exact and rigorous methods which we apply to the criticism of the subject matter of our propaganda. (Some of us, alas, do not apply such criticism even to the alleged facts we attempt to teach.) At last, however, the technic of public health propaganda is coming to be recognized as a proper subject for serious scientific study. Mr. and Mrs. Routzahn, of the Russell Sage Foundation, are at present conducting an intensive investigation along these lines, and we may hope that the next few years will witness an improvement in the machinery for disseminating knowledge in regard to health, comparable to the development of that body of knowledge itself. Editor.

PUBLIC HEALTH AND COST OF LIVING

Special attention has been devoted in recent years to study of the relationship between the economic welfare of groups and communities and their health condition. It has frequently been observed that economic insufficiency and ill health are closely associated, though it is sometimes difficult to ascertain which is the cause and which the effect. The illuminating symposinm on "Poverty and Disease" under the leadership of Professor Winslow[1] at the 1919 National Conference of Social Work, clearly indicated the harmful effects of the operation of this vicious circle.

The infant mortality studies of the Children's Bureau also emphasized the apparent relation between family income and infant mortality. More recently the studies by Dr. Royal Meeker of the Bureau of Labor Statistics on the standard of living in its relation to the health of the family revealed an utter lack of provision in a large proportion of family budgets for adequate medical, hospital, and nursing attention.

It is to be expected, therefore, that the steadily increasing cost of living since 1914 will have some effect on the public health. As pointed out by Doctor Dublin in a

1. 1919 Proceedings of the National Conference of Social Work, p. 153.

memorandum on the relation of wages and prices,[2] "when a dollar buys less goods, many persons have to go without the necessities of life or in other ways must lower their standard of living unless there is a corresponding increase in wages to make up for the lower purchasing power of the dollar."

In March, 1920, wages in New York state showed an increase of 119 per cent over June 1914; but during the same time wholesale prices increased 156 per cent. From experience of previous post-war periods we may expect wages to increase until they reach at least the level of commodity prices.

As observed by Dublin, the mortality statistics have not yet revealed any ill effects of the increased cost of living. Health conditions appear to be even better than before the war. Much of this may be due to the health educational and food conservation propaganda of governmental and private agencies during the war. The remarkable decrease in the death rate from pellagra in the South is an index of improvement in the dietary standard of southern wage earners.

Health workers can be particularly helpful in overcoming the evil effects of a decrease in real wages by instructing the public in the substitution of cheaper foods for the more expensive, also in the principles of diet and other hygienic matters. JULES SCHEVITZ.

THE ANNUAL REPORT

HEALTH officers no longer consider the annual report solely as a means of fulfilling the requirements of the law, to be hurriedly prepared in odd moments, and a task to be delayed as long as possible. They recognize in the annual report a wonderful opportunity for health education and, more especially, they see in it a chance to gain the interest of the enlightened citizenship and busy business man in the work of the health department. Without such support the health officer is losing sight of one of his most valuable opportunities for effective cooperation.

Whether the annual report will serve this purpose depends on the manner in which the facts are presented and the display which they receive, more than in the striking importance of the facts themselves. If it is the desire of the health officer to present a report intended for filing, to be laid away with hundreds of similar reports in the archives of the community or state—and forgotten—he will pay no attention to its form of presentation. He will furnish his long and uninteresting tables, a little descriptive matter, perhaps a few charts, and let it go at that. On the other hand, if he wishes to make his report useful as well as merely to comply with the law, he will take advantage of every known method to render it interesting, attractive, and readable. The most scientific and valuable reports have their usefulness to the community greatly impaired by failure to keep in mind these few facts.

All annual reports should be printed, and should be given as wide a distribution as funds will permit. The health department is supported by public funds, and all the people are entitled to know how the funds are expended. Through this knowledge they will learn something about the problems, successes, and failures of the department. Looking at it from another viewpoint, it is distinctly to the advantage of the health officer to have the contents of his report generally known in the community. Once the people really understand the work his department is undertaking, the health officer has in the annual report a means of overcoming one of his greatest obstacles, namely, lack of funds. It is rare indeed to find an instance of non-support where the people really know what the health department is attempting.

It is evident, therefore, that in addition to serving a rather formal end, the annual report can act as a means of insuring sound financial support for the department in addition to securing an enlightened and intelligent public interest. It should require no great array of facts or display of logic to convince the health officer of the truth of these statements.

In order to receive a hearing by the people the report must compete in appearance, form, and layout with other material reaching the readers. This can be done by using good paper, clear type, plenty of photographs, and other graphic materials; by transferring as many tables as possible in the form of appendices to the end of the report; and by presenting the whole subject in a simple and interesting manner. Matters of scientific interest only should be reprinted separately and made available to those especially interested. JULES SCHEVITZ.

CONJUGAL TUBERCULOSIS

THE question of the extent of conjugal tuberculosis is more significant than the mere determination of the frequency of infection of the consort by the tuberculous mate. It involves the larger questions of whether there is such a thing as adult infection. There has been a tendency in recent years to minimize the importance of conjugal tuberculosis and adult infection; but late studies, particularly by Minnig[1] and Ward[2] appear to challenge these views. Assuming that the normal incidence of tuberculosis in the general population is about 2.7 per cent, the findings of these two authors indicate that there is such a thing as conjugal or marital tuberculosis.

In a review of the literature on the subject Minnig concludes that the findings of all investigators indicate a larger percentage of tuberculosis in the consort of an infected wife or husband than in the general population. In his personal investigations, covering 1,000 successive dispensary cases, of whom 502 were married, he discovered active tuberculosis in husband and wife in 44 cases, or 8.7 per cent. Of the 44 cases, half of the consorts had died of tuberculosis.

Ward, in England, after a study extending over several years, finds that 58 per cent of the consorts whose mates have tuberculosis sooner or later develop signs and symptoms of active tuberculosis, though a great many of these recover. The following table prepared from Ward's data shows that while 58 per cent of the consorts of infected mates develop tuberculosis, only 20 per cent of all other contacts in the family become actively diseased.

RESULTS OF EXAMINATIONS OF CONSORTS OF INFECTED MATES, AND OTHER CONTACTS

Distribution	Number Examined	Tuberculous		Suspects		Negative	
		No.	Per cent	No.	Per cent	No.	Per cent
Wives (Husbands Tuberculous)	120	66	55	12	10	42	35
Husband (Wife Tuberculous)	36	25	69	4	11	7	20
Total	156	91	58	16	10	49	32
Other Contacts	1,057	219	20	284	17	564	53

2. Ward, E.: Conjugal Tuberculosis, Lancet, London, 1920, cxcvii, 606.

It is to be remembered that these figures refer almost entirely to patients in the laboring classes; also, that no allowance is made for cases in which both mates had the disease previous to marriage. The apparent wide difference in the percentage of marital infection shown in Ward's figures from those of other investigators may possibly be due to varying standards of classification employed.

If it be true that marital infection is as prevalent as these and other figures indicate, and that adult infection is frequent, it is essential that our tuberculosis workers modify their present methods in the care of the tuberculous in their homes. JULES SCHEVITZ.

BARBER SHOP DANGERS

FROM all quarters of the country there has come a growing insistence for greater protection to the barber shop patron against infection, particularly of venereal origin. State health departments are recognizing the menace of careless methods in the barber shop, especially in the use of infected implements and the employment of infected barbers, and are regulating against these dangers. Most notable have been the efforts of the Louisiana Health Department.

A correspondent in England* suggests protection from another angle in demanding that the law should make it a criminal offense punishable by imprisonment, for any person to use a barber's shop while suffering from or under treatment for certain diseases. A certificate of health should be required before diseased individuals may use the shop. He presents the following interesting comments on the dangers in the barber shop:

In the present age of reform it is remarkable how our reformers seem to have greatly neglected the dangers to public health that are ever present in the barber's shop, a place resorted to by the healthy and by the diseased, where you wait your turn and take your chance. One and all come into contact with the same lather, brush, razor, sponge, and towel. And what a chance you take,—a chance of contracting some specific disease, it may be a disease fraught with terrible consequences, not only to yourself but to others. You may think that the odds against this happening are remote. Even if they are remote, is it right to take such odds?

That dangers referred to are real and operative can be testified by physicians and health workers everywhere. The methods employed in the sterilization of razors and brushes, especially after being used on infected individuals, and also the not uncommon occurrence of an infected barber attending to a healthy patron, are serious menaces to the public health that demand most careful attention. JULES SCHEVITZ.

A CHANGE IN NAME

IN line with similar action taken by other state tuberculosis organizations, the Board of Managers of the New York State Charities Aid Association has changed the name of the Association's Committee on Prevention of Tuberculosis to the Committee on Tuberculosis and Public Health. According to the Committee, the change in name does not imply change in objects or methods but is simply a recognition of what has been the fact for several years.

The scope of anti-tuberculosis work has steadily broadened in the light of experience. The agreement between the National Tuberculosis Association and its auxiliaries, under which the Christmas seals are sold, contains a working definition of anti-tuberculosis work which for some years has recognized several phases of child hygiene as essential elements in it. Recently the definition was further amended so as to include various forms of child hygiene. JULES SCHEVITZ.

BUNK AND BUBONIC PLAGUE

Writing under the above caption in the Chicago *Tribune* of September 1, W. A. Evans, M.D., gives the following history of the introduction and spread of plague in this country:

Bubonic plague has the firmest foothold on this country that it has ever had. It found it way into California in 1900. Thanks to interference by the courts and by powerful business, political, and religious influences, it became so firmly intrenched during the three years that no effort to control it was made, that an occasional animal infected with plague is found, and just one year ago there was a small human outbreak.

Having got a foothold in New Orleans several years ago, the disease has held on. Last November there was another human outbreak. This year cases of human plague have been reported from several other gulf ports. The disease has been in the country for twenty years, and not all the effort and expense have availed to eradicate it.

This experience teaches two lessons. The first is that bubonic plague does not menace our people with any great disaster. The second is that the disease, once it gets a foothold among the rats and certain small flea infested wild animals, is only cleaned out with the greatest difficulty. Cities back of the seaboard are sitting back in easy satisfaction. They say they are safe because though the disease has been in the United States twenty years it has never got fifty miles from the seaboard.

Almost overnight a railroad train carried the infection from San Francisco to Los Angeles about fifteen years ago. The distance from San Francisco to Los Angeles by rail is almost as great as the distance from New Orleans to Chicago.

Dr. W. H. Kellogg in his report of the Berkeley epidemic of 1919 said that the seaboard cities were not in great danger of pneumonic plague, the most terrible variety of the disease, but woe unto the cities of the northern and eastern sections of the United States should the infection ever spread to their rats.
